TABLES AND FIGURES

FOREWORD

This report presents findings from the 2014 Ghana Demographic and Health Survey (GDHS), a nationally representative survey of 9,396 women age 15-49 and 4,388 men age 15-59 from 11,835 interviewed households. The primary purpose of the GDHS was to generate recent and reliable information on fertility, family planning, infant and child mortality, maternal and child health, and nutrition. In addition, the survey collected information on malaria treatment, prevention, and prevalence among children age 6-59 months; blood pressure among adults; anaemia among women and children; and HIV prevalence among adults. This information is essential for making informed policy decisions and for planning, monitoring, and evaluating programmes related to health in general, and reproductive health in particular, at both the national and regional levels.

The 2014 GDHS is the sixth in a series of population and health surveys conducted in Ghana as part of the global Demographic and Health Surveys (DHS) Program. The survey was implemented by the Ghana Statistical Service (GSS), the Ghana Health Service (GHS), and the National Public Health Reference Laboratory (NPHRL) of the GHS. Financial support for the survey was provided by the United States Agency for International Development (USAID), the Global Fund through the Ghana AIDS Commission (GAC) and the National Malaria Control Programme (NMCP), the United Nations Children's Fund (UNICEF), the United Nations Development Programme (UNDP), the United Nations Population Fund (UNFPA), the International Labour Organization (ILO), the Danish International Development Agency (DANIDA), and the Government of Ghana. ICF International provided technical assistance through The DHS Program, a USAID-funded project offering support and technical assistance in the implementation of population and health surveys in countries worldwide.

ACRONYMS

ACT   artemisinin-based combination therapy
AIDS   acquired immunodeficiency syndrome
ANC   antenatal care
ARI   acute respiratory infection
ASFR   age-specific fertility rate
BCG   Bacille Calmette-Guerin
BMI   body mass index
BOG   Bank of Ghana
CAFE   computer assisted field editing
CBR   crude birth rate
CDC   Centers for Disease Control and Prevention
CDD   Control of Diarrhoeal Diseases
CEDAW   Convention on the Elimination of All Forms of Discrimination against Women
CHPS   community-based health planning and services
CSPro   Census and Survey Processing System
CPR   contraceptive prevalence rate
DANIDA   Danish International Development Agency
DBS   dried blood spot
DFID   Department for International Development
DOTS   directly observed treatment, short-course
EA   enumeration area
ELISA   enzyme-linked immunosorbent assay
EQA   external quality assurance
GAR   gross attendance ratio
GAC   Ghana AIDS Commission
GDHS   Ghana Demographic and Health Survey
GDP   gross domestic product
GETFUND   Ghana Education Trust Fund
GFR   general fertility rate
GHS   Ghana Health Service
GPI   gender party index
GPS   Global Positioning System
GSS   Ghana Statistical Office
HCT   HIV counselling and testing
HepB   hepatitis B
HIV   human immunodeficiency virus
IFSS   Internet File Streaming System
ILO   International Labour Organization
IMCI   integrated management of childhood illnesses
IPTp   intermittent preventive treatment
IRS   indoor residual spraying
ITN   insecticide-treated net

IUD	intrauterine device
IYCF	Infant and Young Child Feeding
LAM	lactational amenorrhoea method
LEAP	livelihood empowerment against poverty
LPG	liquid petroleum gas
LLIN	long-lasting insecticidal net
MDG	Millenium Development Goal
MoH	Ministry of Health
MWRWH	Ministry of Water Resource Works and Housing
NACP	National AIDS/STI Control Programme
NAR	net attendance ratio
NDPC	National Development Planning Commission
NGO	nongovernmental organisation
NHIS	National Health Insurance Scheme
NMCP	National Malaria Control Programme
NMIMR	Noguchi Memorial Institute for Medical Research
NPHRL	National Public Health and Reference Laboratory
ORS	oral rehydration salt
ORT	oral rehydration therapy
PAHO	Pan American Health Organization
PHC	population and housing census
PLHIV	people living with HIV/AIDS
PMI	President's Malaria Initiative
PMTCT	prevention of mother-to-child transmission
RDT	rapid diagnostic test
RHF	recommended home fluid
RTI	reproductive tract infection
SHS	secondhand smoke
STI	sexually transmitted infection
TB	tuberculosis
TFR	total fertility rate
UNDP	United Nations Development Programme
UNFPA	United Nations Population Fund
UNICEF	United Nations Children's Fund
USAID	United States Agency for International Development
VAD	vitamin A deficiency
WASH	water, sanitation and hygiene
WHO	World Health Organization

MILLENNIUM DEVELOPMENT GOAL INDICATORS

Millennium Development Goal Indicators

Ghana 2014

Indicator	Sex		Total
	Male	Female	
1. Eradicate extreme poverty and hunger			
1.8 Prevalence of underweight children under age 5	10.6	11.6	11.0
2. Achieve universal primary education			
2.1 Net attendance ratio in primary education[1]	69.6	69.6	69.6
2.3 Literacy rate of 15 to 24-year-olds[2]	89.3[a]	80.9	85.1[b]
3. Promote gender equality and empower women			
3.1 Ratio of girls to boys in primary, secondary, and tertiary education			
3.1a Ratio of girls to boys in primary education[3]	na	na	1.0
3.1b Ratio of girls to boys in secondary education[3]	na	na	0.9
3.1c Ratio of girls to boys in tertiary education[3]	na	na	1.0
4. Reduce child mortality			
4.1 Under-5 mortality rate[4]	78	62	60
4.2 Infant mortality rate[4]	52	43	41
4.3 Proportion of 1-year-old children immunized against one dose of measles	88.2	90.3	89.3
5. Improve maternal health			
5.2 Percentage of births attended by skilled health personnel[5]	na	na	73.7
5.3 Contraceptive prevalence rate[6]	na	26.7	na
5.4 Adolescent birth rate[7]	na	76.3	na
5.5a Antenatal care coverage: at least one visit[8]	na	97.0	na
5.5b Antenatal care coverage: four or more visits[9]	na	87.3	na
5.6 Unmet need for family planning	na	29.9	na
6. Combat HIV/AIDS, malaria, and other diseases			
6.1 HIV prevalence among the population age 15-24	0.2	1.5	0.8
6.2 Condom use at last high-risk sex[10]	39.3	19.2	29.3
6.3 Percentage of the population age 15-24 with comprehensive correct knowledge of HIV/AIDS[11]	27.2	19.9	23.6
6.4 Ratio of school attendance of orphans to school attendance of non-orphans age 10-14	0.97	0.92	0.94
6.7 Percentage of children under 5 sleeping under insecticide-treated bed nets	47.5	45.6	46.6
6.8 Percentage of children under 5 with fever who are treated with appropriate antimalarial drugs[12]	46.8	50.6	48.5

Indicator	Urban	Rural	Total
7. Ensure environmental sustainability			
7.8 Percentage of population using an improved drinking water source[13]	57.0	71.4	64.2
7.9 Percentage of population with access to improved sanitation[14]	20.5	9.6	15.0

na = Not applicable

[1] The ratio is based on reported attendance, not enrollment, in primary education among primary school age children (6-11 years). The rate also includes children of primary school age enrolled in secondary education. This is a proxy for MDG indicator 2.1, Net enrollment ratio.

[2] Refers to respondents who attended secondary school or higher or who could read a whole sentence or part of a sentence

[3] Based on reported net attendance, not gross enrollment, among 6-11-year-olds for primary, 12-17-year-olds for secondary, and 18-24-year-olds for tertiary education

[4] Expressed in terms of deaths per 1,000 live births. Mortality by sex refers to a 10-year reference period preceding the survey. Mortality rates for males and females combined refer to the five-year period preceding the survey.

[5] Among births in the five years preceding the survey

[6] Percentage of currently married women age 15-49 using any method of contraception

[7] Equivalent to the age-specific fertility rate for women age 15-19 for the three years preceding the survey, expressed in terms of births per 1,000 women age 15-19

[8] With a skilled provider

[9] With any health care provider

[10] High-risk sex refers to sexual intercourse with a non-marital, non-cohabitating partner. Expressed as a percentage of men and women age 15-24 who had higher-risk sex in the past 12 months.

[11] Comprehensive knowledge means knowing that consistent use of a condom during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about transmission or prevention of the AIDS virus.

[12] Measured as the percentage of children age 0-59 months who were ill with a fever in the two weeks preceding the interview and who received any antimalarial drug

[13] Percentage of de jure population whose main source of drinking water is a household connection (piped), public tap or standpipe, tubewell or borehole, protected dug well, protected spring, or rainwater collection.

[14] Percentage of de jure population whose household has a flush toilet, ventilated improved pit latrine, pit latrine with a slab, or composting toilet and does not share its facility with other households

[a] Restricted to men in a subsample of households selected for the male interview

[b] The total calculated as the simple arithmetic mean of the percentages in the columns for male and females

GHANA

INTRODUCTION

<div style="text-align: right; font-size: 2em;">1</div>
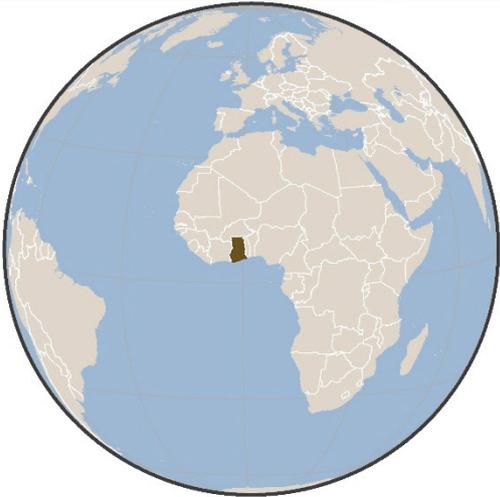

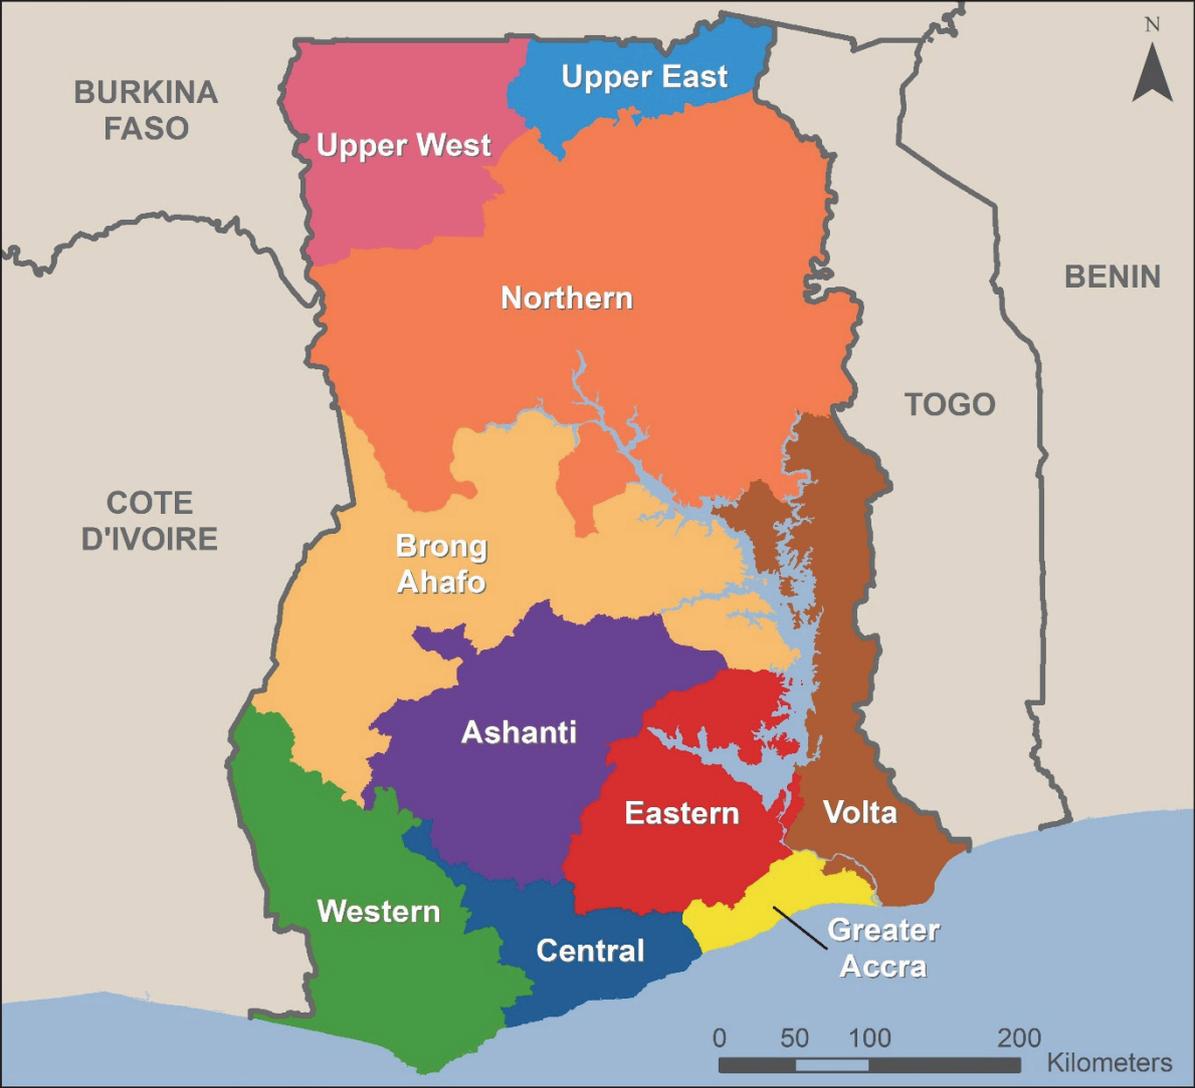

1.1 GEOGRAPHY, HISTORY, AND ECONOMY

1.1.1 Geography

T he Republic of Ghana is centrally located on the West African coast. It has a total land area of 238,537 square kilometres, and it is bordered by three French-speaking countries: Togo on the east, Burkina Faso on the north and northwest, and Côte d'Ivoire on the west. The Gulf of Guinea lies to the south and stretches across the 560-kilometre coastline.

Ghana is a lowland country except for a range of highlands on the eastern border. The highest elevation is Mt. Afadjato, 884 metres above sea level, found in the Akuapem-Togo ranges, west of the Volta River. Ghana can be divided into three ecological zones: the low, sandy coastal plains, with several rivers and streams; the middle and western parts of the country, characterised by a heavy canopy of semi-deciduous rainforests, with many streams and rivers; and a northern savannah, which is drained by the Black and White Volta Rivers. The Volta Lake, created by the hydroelectric dam in the East, is one of the largest artificial lakes in the world.

Ghana has a tropical climate with temperatures and rainfall patterns that vary according to distance from the coast and elevation. The eastern coastal area is comparatively dry, the southwestern corner is hot and humid, and the north of the country is hot and dry. The average annual temperature is about 26ºC (79ºF). There are two distinct rainy seasons in the southern and middle parts of the country, from April to June and September to November. The North is, however, characterised by one rainfall season that begins in May, peaks in August, and lasts until September. Annual rainfall ranges from about 1,015 millimetres (40 inches) in the North to about 2,030 millimetres (80 inches) in the Southwest. The *harmattan*, a dry dusty desert wind, blows from the northeast and covers much of the country between December and March, lowering the humidity and visibility, and also creates very warm days and cool nights in the North. In the South, the effects of the *harmattan* are felt mainly in January.

1.1.2 History

Ghana gained independence from British colonial rule on 6 March 1957, and became a republic in the British Commonwealth of Nations on 1 July 1960 with Accra as its administrative and political capital. Ghana operates a multi-party democracy with an executive president who is elected for a term of four years with a maximum of two terms. There is a parliament elected every four years, an independent judiciary, and a vibrant media.

There are 10 administrative regions in Ghana: Western, Central, Greater Accra, Volta, Eastern, Ashanti, Brong Ahafo, Northern, Upper East, and Upper West. Ghana's population was estimated at 27 million in 2014 (GSS 2013a). The Ashanti, Eastern, and Greater Accra regions together constitute about 50 percent of the country's population. Upper East is the least populated region, accounting for 2 percent of the total population of Ghana. The regions are subdivided into 216 districts to ensure equitable resource allocation and efficient, effective administration at the local level (GSS 2013b).

The Ghanaian population is made up of several ethnic groups, with the Akans constituting the largest group (48 percent), followed by the Mole-Dagbani (17 percent), Ewe (14 percent), Ga-Dangme (7 percent), and others (GSS 2013b).

1.1.3 Economy

The structure of the Ghanaian economy has seen minimal changes over the past two decades. The agriculture sector, previously the largest contributor to the Ghanaian economy, has been overtaken by the service and industry sectors. By 2014, the service sector was the fastest growing sector of the economy, contributing 52 percent of the gross domestic product (GDP), followed by the industry sector, at 27 percent, and the agriculture sector, at 22 percent. In 2014, the service sector recorded its highest growth, of 6 percent, followed by the agricultural sector with 5 percent growth, and the industry sector with 1 percent growth (GSS 2015).

Overall, the 2014 real annual GDP grew by 4 percent compared with 7 percent growth recorded in 2013 (GSS 2015).

About 45 percent of the economically active population are engaged in agriculture, and 41 percent provide services. A high proportion of the employed population of Ghana works in the informal sector, the majority being self-employed (GSS 2014).

The leading export commodities of Ghana are cocoa, gold, and timber. Recently, the economy has diversified to the export of non-traditional commodities such as pineapples, bananas, yams, and cashew nuts. The tourism industry contributes substantially to the country's economy, as a key driver of economic growth. The industry is currently the third largest foreign exchange earner after merchandise exports and remittances from abroad and has become one of the most important and fastest growing sectors of the Ghanaian economy (BOG 2007).

Over the past decade, the government of Ghana has embarked on various economic and poverty-reduction programmes designed to improve the living conditions of its citizenry. The Livelihood Empowerment Against Poverty (LEAP) programme was introduced in 2007 and, in 2008, the poor began to receive cash support on a monthly basis.

Many changes have occurred in the education sector over the past 15 years. Pre-school education has officially been incorporated into the basic education as a part of primary and junior high school. All primary schools are required to have nurseries or kindergartens. In the 2005-2006 academic year, the government absorbed school fees for all pupils enrolled in basic public schools, resulting in free education (Darko et al. 2009). During the same period, a school feeding programme was introduced on a pilot basis and has since been extended to all basic schools. While the programme aims at improving the nutritional status of school pupils, a secondary effect has been to increase enrolment.

At the secondary level, the senior high school was introduced in the 2007-2008 academic year, expanding the system from three to four years, but this policy was reversed in 2009.

The introduction of the Ghana Education Trust Fund (GETFUND), a public trust set up by an Act of Parliament in the year 2000, has brought many improvements to the education system. The fund provides educational infrastructure such as buildings to support the country's tertiary institutions and, as a result, has improved teaching and learning within these institutions.

1.2 DEMOGRAPHIC PROFILE

Sources of demographic information about the Ghanaian population include censuses, surveys, and administrative data. Population censuses provide more comprehensive demographic information than other sources. Ghana has completed five censuses since gaining independence in 1957. The first one was conducted in 1960 and reported a population of 6.7 million. The 1970 census recorded 8.6 million people, and the 1984 census, 12.3 million. In 2000, the Population and Housing Census (PHC) recorded 18.9 million, while in the 2010 PHC, 24.7 million were recorded. The average annual growth rate between 2000 and 2010 was 2.5 percent. The growth rates over individual periods were 2.4 percent, 2.6 percent, 2.7

percent, and 25 percent during 1960-1970, 1970-1984, 1984-2000, and 2000-2010, respectively (Table 1.1).

The population density has increased over the years from 29 persons per square kilometre (persons/km²) in 1960 to 103 persons/km² in 2010. The proportion of the population living in urban areas has more than doubled in the last five decades, expanding from 23 percent in 1960 to 51 percent in 2010.

The sex ratio of 102.2 males per 100 females recorded in 1960 has declined to 95.2 males per 100 females in 2010. The proportion of the population under age 15 has also decreased from 45 percent in 1960 to 38 percent in 2010 (Table 1.1), while the proportion of the population age 65 years and older increased from 3 percent to 5 percent over the same period (data not shown separately). Over the last five decades, life expectancy at birth has increased from 38 years to 60 years among males and from 43 years to 63 years among females (GSS 1979, 1985, 2002, and 2013b).

Table 1.1 Basic demographic indicators

Indicators	Pop census 1960	Pop census 1970	Pop census 1984	Pop & housing census 2000	Pop & housing census 2010
Population (millions)	6.7	8.6	12.3	18.9	24.7
Annual growth rate (percent)	na	2.4	2.6	2.7	2.5
		(1960-1970)	(1970-1984)	(1984-2000)	(2000-2010)
Density (population/km²)	29	36	52	79	103
Percent urban	23	29	32	44	51
Sex Ratio	102.2	98.5	97.3	97.9	95.2
Population under 15 years	45	48	46	42	40
Life expectancy (years)					
Male	38	45	50	55	60
Female	43	48	54	60	63

na= Not applicable
Sources: Ghana Statistical Service (GSS), 1979, 1985, 2002, and 2013b

Population and housing censuses are resource intensive, expensive to implement, and generally take place at 10-year intervals. Sample surveys are, therefore, important for informing demographic profiles during inter-censal periods. They are conducted to collect a wide range of data to complement the census data. Sample surveys are cheaper and can be implemented more frequently and at regular intervals. The Ghana Demographic and Health Survey (GDHS), which is a household survey, is an example of a sample survey data collection tool.

Another important but often neglected data source in Ghana is the administrative data. These data are generated as a by-product of events and processes, and they provide relatively up-to-date information to fill gaps in both censuses and surveys. Vital registration systems (birth and death registration), health systems (immunisations), and education data (enrolment) are examples of administrative data.

1.3   POPULATION POLICY AND REPRODUCTIVE HEALTH PROGRAMMES

The National Population Policy of Ghana was formulated in 1969 in recognition of the simultaneous high growth of population and fertility. The policy was revised in 1994 because of its modest impact after 25 years of implementation. The revision took into account emerging issues such as HIV/AIDS, population and the environment, and concerns about the elderly and children. It developed new strategies that would ensure the achievement of its goals and objectives. The revision of the population policy also entailed concerted effort to systematically integrate population variables in all areas of national development and programme planning (NPC 1994).

Some selected targets of the revised population policy included the following:

- Reduce the total fertility rate (TFR) from 5.5 in 1993 to 5.0 by 2000, 4.0 by 2010, and 3.0 by 2020

- Achieve a contraceptive prevalence rate (CPR) with modern methods of 15 percent by the year 2000, 28 percent by 2010, and 50 percent by the year 2020

- Reduce the population growth rate from about 3 percent per annum to 1.5 percent per annum by the year 2020

- Increase life expectancy to age 70 years by the year 2020 (NPC 1994)

The attainment of these population targets is recognised as an integral component of the national strategy to accelerate economic development, eradicate poverty, and enhance the quality of life of all Ghanaians.

In collaboration with the United Nations Population Fund (UNFPA), the United States Agency for International Development (USAID), the World Bank, and other development partners, Ghana has implemented several projects aimed at reducing reproductive health problems among its population. Support from these agencies has targeted policy coordination, implementation, and service delivery.

The government is committed to improving access and equity of access to essential health care services. The priority areas identified include HIV/AIDS and other sexually transmitted infections (STIs), malaria, tuberculosis, guinea worm disease, poliomyelitis, reproductive health, maternal and child health, accidents and emergencies, noncommunicable diseases, oral health and eye care, and specialised services. Emphasis is also being placed on regenerative health and preventive as well as community-based health care services. This has necessitated the introduction of the Community-based Health Planning and Services (CHPS) programme in which trained nurses are stationed in selected communities to provide health care services to members of the communities.

In response to the HIV/AIDS epidemic, the government of Ghana set up the National AIDS Commission to oversee the implementation of HIV/AIDS programmes using a multi-sectoral approach and to ensure that HIV/AIDS prevention education, treatment, care, and support reach every corner of the country. The Ghana Health Service (GHS) also set up the National AIDS Control Programme (NACP) to offer HIV/AIDS prevention and education services. The combined efforts of all stakeholders ensured the implementation of the Ghana HIV/AIDS Strategic Framework: 2001-2005 (World Bank 2003). These collaborative efforts have had a positive impact. In 2013, only 1.3 percent of Ghanaian adults were HIV positive (GHS 2014).

The Roll Back Malaria, tuberculosis (TB-DOTS), and integrated management of childhood illnesses (IMCI) are also priority areas under the country's health care system. Other health interventions instituted as part of the government's efforts to make health care accessible and affordable to all include the introduction of the National Health Insurance Scheme (NHIS) and a free maternal care programme (United Nations 2008).

Sustainable accessibility and availability of improved water and sanitation are essential to the health of a population. Therefore, extensive efforts are being made in Ghana to ensure universal access to safe drinking water and improved sanitation facilities by the year 2025 (MWRWH 2009). The Ghana WASH Project, under the auspices of the Ministry of Local Government and Rural Development, is a USAID-funded initiative. The goal of the project is to improve water and sanitation facilities and to increase hygiene education among rural and peri-urban communities to prevent the spread of diseases like diarrhoea, dysentery, cholera, and, recently, Ebola. The Ghana WASH Project is supported by a number of

agencies, including Relief International, the Adventist Development Relief Agency, and Winrock International.

1.4 OBJECTIVES AND ORGANISATION OF THE SURVEY

The primary objective of the 2014 GDHS was to generate recent reliable information on fertility, family planning, infant and child mortality, maternal and child health, and nutrition. In addition, the survey collected specialised data on malaria treatment, prevention, and prevalence among children age 6-59 months; blood pressure among adults; anaemia among women and children; and HIV prevalence among adults. This information is essential for making informed policy decisions and for planning, monitoring, and evaluating programmes related to health in general, and reproductive health in particular, at both the national and regional levels. Analysis of data collected in the 2014 GDHS provides updated estimates of basic demographic and health indicators covered in the earlier rounds of the 1988, 1993, 1998, 2003, and 2008 surveys.

The GDHS will assist policymakers and programme managers in evaluating and designing programmes and strategies for improving the health of Ghana's population. The 2014 GDHS also provides comparable data for long-term trend analysis in Ghana, since the surveys were implemented by the same organisation, using similar data collection procedures. Furthermore, the survey adds to the international database on demographic and health–related information for research purposes.

The survey was implemented by the Ghana Statistical Service (GSS), the Ghana Health Service (GHS), and the National Public Health Reference Laboratory (NPHRL) of the GHS. The Noguchi Memorial Institute for Medical Research (NMIMR) performed the external quality assurance testing for the malaria and HIV testing component of the 2014 Ghana DHS survey. Financial support for the survey was provided by the United States Agency for International Development (USAID), the Global Fund through the Ghana AIDS Commission (GAC) and the National Malaria Control Programme (NMCP), the United Nations Children's Fund (UNICEF), the United Nations Development Programme (UNDP), the United Nations Population Fund (UNFPA), the International Labour Organization (ILO), the Danish International Development Agency (DANIDA), and the Government of Ghana. ICF International provided technical assistance through The DHS Program, a USAID-funded project offering support and technical assistance in the implementation of population and health surveys in countries worldwide.

In addition to the main survey, a follow up study on family planning was conducted by a different team on a subsample of households selected for the GDHS survey. The main goal of this study was to better understand the underlying factors behind observed variations in unmet need and to strengthen assessments of the demand for family planning. The research team re-interviewed a subsample of the selected GDHS original female respondents in 13 clusters who consented to be re-interviewed. Women age 15-44 who were not currently using family planning or who reported not wanting their current pregnancy or their most recent live birth were eligible for the follow-up survey. Additionally, a randomly selected 10 percent of current female users of family planning age 15-44 in those clusters also were eligible for the study. Results of the follow up study on unmet need for family planning are not discussed in this report and will be published in a separate report.

1.5 SAMPLE DESIGN

The sampling frame used for the 2014 GDHS is an updated frame from the 2010 Ghana Population and Housing Census provided by the Ghana Statistical Service (GSS 2013b). The sampling frame excluded nomadic and institutional populations such as persons in hotels, barracks, and prisons.

The 2014 GDHS followed a two-stage sample design and was intended to allow estimates of key indicators at the national level as well as for urban and rural areas and each of Ghana's 10 administrative regions. The first stage involved selecting sample points (clusters) consisting of enumeration areas (EAs)

delineated for the 2010 PHC. A total of 427 clusters were selected, 216 in urban areas and 211 in rural areas.

The second stage involved the systematic sampling of households. A household listing operation was undertaken in all the selected EAs in January-March 2014, and households to be included in the survey were randomly selected from the list. About 30 households were selected from each cluster to constitute the total sample size of 12,831 households. Because of the approximately equal sample sizes in each region, the sample is not self-weighting at the national level, and weighting factors have been added to the data file so that the results will be proportional at the national level.

All women age 15-49 who were either permanent residents of the selected households or visitors who stayed in the household the night before the survey were eligible to be interviewed and have their blood pressure measured.

In half of the households, all men age 15-59 who were either permanent residents of the selected households or visitors who stayed in the households the night before the survey were eligible to be interviewed. In addition, in the subsample of households selected for the male survey:

- blood pressure measurements were performed among eligible men who consented to being tested;

- children age 6-59 months were tested for anaemia and malaria with the parent's or guardian's consent;

- eligible women who consented were tested for anaemia;

- blood samples were collected for laboratory testing of HIV from eligible women and men who consented; and

- height and weight information was collected from eligible women, men, and children age 0-59 months.

1.6 QUESTIONNAIRES

Three questionnaires were used for the 2014 GDHS: the Household Questionnaire, the Woman's Questionnaire, and the Man's Questionnaire. These questionnaires, which were based on standard Demographic and Health Survey (DHS) questionnaires, were adapted to reflect the population and health issues relevant to Ghana. Comments on the questionnaires were solicited from various stakeholders representing government ministries and agencies, nongovernmental organisations, and international donors. The definitive questionnaires were first prepared in English; they were then translated into the major local languages, namely Akan, Ga, and Ewe.

The Household Questionnaire was used to list all the members of and visitors to the selected households. Basic demographic information was collected on the characteristics of each person listed, including his or her age, sex, marital status, education, and relationship to the head of the household. For children under age 18, parents' survival status was determined. The data on age and sex of household members obtained in the Household Questionnaire were used to identify women and men who were eligible for individual interviews. The Household Questionnaire also included questions on child education as well as the characteristics of the household's dwelling unit, such as source of water, type of toilet facilities, materials used for the floor of the dwelling unit, and ownership of various durable goods.

The Woman's Questionnaire was used to collect information from all eligible women age 15-49. These women were asked questions on the following topics:

- Background characteristics (age, education, media exposure, etc.)

- Birth history and child mortality

- Residence of children under age 18 not living with their parents

- Knowledge and use of family planning methods

- Fertility preferences

- Antenatal, delivery, and postnatal care

- Breastfeeding and infant feeding practices

- Vaccinations and childhood illnesses

- Marriage and sexual activity

- Women's work and husbands' background characteristics

- Women's empowerment indicators, maternity leave, and bridewealth

- Knowledge, awareness, and behaviour regarding HIV/AIDS and other sexually transmitted infections (STIs)

- Knowledge, attitudes, and behaviour related to other health issues (e.g., smoking, tuberculosis, and blood pressure)

In half of the selected households, the Man's Questionnaire was administered to all men age 15-59. The Man's Questionnaire collected much of the same information found in the Woman's Questionnaire but was shorter because it did not contain a detailed reproductive history or questions on maternal and child health.

1.7 BLOOD PRESSURE MEASUREMENT, ANTHROPOMETRY, ANAEMIA TESTING, AND HIV TESTING

In half of the households selected for the male survey, the 2014 GDHS incorporated several *biomarkers*: blood pressure measurement, anthropometry, anaemia testing, and HIV testing. The survey protocol, including biomarker collection, was reviewed and approved by the Ghana Health Service Ethical Review Committee and the Institutional Review Board of ICF International.

Blood pressure. During the individual interview, three blood pressure measurements were taken from consenting women age 15-49 in all the selected households and from consenting men age 15-59 in the subsample of households selected for the male survey (half of the households). Blood pressure was measured using the LIFE SOURCE® UA-767 Plus blood pressure monitor: a digital oscillometric blood pressure measuring device with automatic upper-arm inflation and automatic pressure release. Measurements were taken at intervals of 10 minutes or more. The average of the second and third measurements was used to classify the respondent with respect to hypertension, according to internationally recommended categories (WHO 1999). The results, as well as information about the symptoms of high blood pressure and ways in which it can be prevented, were provided to the respondent via a blood pressure reporting form.

Anthropometry. In the subsample of households selected for the male survey, height and weight measurements were recorded for children age 0-59 months, women age 15-49, and men age 15-59.

Anaemia testing. Blood specimens for anaemia testing were collected in half of the selected households (the subsample selected for the male survey) from women age 15-49 who voluntarily consented to be tested and from all children age 6-59 months for whom consent was obtained from their parents or the adult responsible for the children. Blood samples were drawn from a drop of blood taken

from a finger prick (or a heel prick in the case of children age 6-11 months) and collected in a microcuvette. Haemoglobin analysis was carried out on-site using a battery-operated portable HemoCue analyser.

All households in which anthropometry and/or anaemia testing was conducted were given an Anaemia and Height and Weight Brochure containing information on height and weight measurements of all children measured, as well as information on causes and prevention of anaemia. The haemoglobin test results for all children tested in the household were entered into the Malaria and Anaemia Brochure and given to the parent or responsible adult. Finally, an anaemia referral form was given to facilitate immediate treatment at a nearby health facility of children with a haemoglobin level less than 7.0 g/dl, of nonpregnant women with a haemoglobin level less than 7.0 g/dl, and of pregnant women with a haemoglobin level less than 9.0 g/dl.

Malaria testing. In half of the selected households, children age 6-59 months were also tested for malaria in the field using SDBioline Malaria Ag P.f/Pan, a rapid diagnostic test (RDT). This high-sensitivity and high-specificity test detects malaria antigens from capillary blood samples. The children's RDT results were recorded in the Malaria and Anaemia Brochure and given to the parent or responsible adult. In accordance with the Ghanaian national treatment guidelines, children who tested positive for malaria by the RDT and did not exhibit symptoms of severe malaria were provided with ACT (excluding children who were on ACT treatment at the time of the survey or who had taken ACT in the previous two weeks prior to the testing). Children showing signs or symptoms of severe malaria were given a malaria referral form to seek immediate treatment at a nearby health facility.

In addition, blood was collected on glass slides from the same children who were tested with RDT and sent to the National Public Health Reference Laboratory (NPHRL) in Accra for malaria microscopy through reading of thick-smear slides. As mentioned above, the Noguchi Memorial Institute for Medical Research (NMIMR) performed the external quality assurance testing (EQA) for the malaria testing component of the 2014 Ghana DHS survey.

HIV testing. Health technicians collected finger-prick blood specimens to test for HIV in women age 15-49 and men age 15-59 in the subsample of households selected for the male survey who consented to be tested. The protocol for blood specimen collection and analysis was based on the anonymous linked protocol developed for The DHS Program. This protocol allows for merging of HIV test results with the sociodemographic data collected in the individual questionnaires after removal of all information that could potentially identify an individual.

Health technicians explained the procedure, the confidentiality of the data, and the fact that the test results would not be made available to the respondent. If a respondent consented to HIV testing, five blood spots from the finger prick were collected on a filter paper card to which a barcode label unique to the respondent was affixed. A duplicate label was attached to the Biomarker Section of the Household Questionnaire. A third copy of the same barcode was affixed to a dried blood spot transmittal sheet to track the blood samples from the field to the laboratory.

Respondents were asked whether they would consent to having the laboratory store their blood sample for future unspecified testing. If respondents did not consent to additional testing using their sample, it was indicated on the Biomarker Section of the Household Questionnaire that they refused additional tests using their specimen, and the words *no additional testing* were written on the filter paper card. Each respondent, whether he or she provided consent or not, was given an informational brochure on HIV and a list of nearby sites providing HIV counselling and testing (HCT) services.

Blood samples were dried overnight and packaged for storage the following morning. Samples were periodically collected from the field and transported to NPHRL. Once they arrived at the central laboratory, each blood sample was logged into the CSPro HIV Test Tracking System database, given a laboratory number, and stored at -20˚C until tested.

The HIV testing protocol stipulated that blood could be tested only after questionnaire data collection had been completed, data had been verified and cleaned, and all unique identifiers other than the anonymous barcode number had been removed from the data file.

The testing algorithm calls for testing all samples on the first assay test, the Vironostika® HIV Ag/Ab (Biomérieux) enzyme-linked immunoassay (ELISA). A negative result is recorded as negative. All positives are subjected to a second ELISA, the Enzygnost® HIV Integral II assay (Siemens). Positive samples on the second test are recorded as positive. If the first and second tests are discordant, the two ELISAs are repeated in parallel. If the results remain discordant, a third confirmatory blot assay, the Inno-Lia HIV I/II Score (Innogenetics, Ghent, Belgium), is used. The final result is recorded as positive if the blot assay confirms it to be positive and negative if the blot assay confirms it to be negative. If the blot assay results are indeterminate, the sample is recorded as indeterminate. External quality assurance testing was done by the Noguchi Memorial Institute for Medical Research.

After HIV testing has been completed, the HIV test results for the 2014 GDHS were entered into a spreadsheet with a barcode as the unique identifier. The barcode was used to link the HIV test results with the data from the individual interviews. Data from the HIV results were then linked to demographic and health data.

1.8 PRETEST

Ten women and five men participated in the pretest training and field practice of the GDHS survey protocol and instruments over a three-week period, 9-28 June, 2014. Most participants had participated in previous GDHS surveys. During the first week of training, seven health technicians (one woman and six men) hired through the National Public Health and Reference Laboratory in Accra, were trained together with the interviewers on general interviewing techniques and how to conduct interviews using the Household Questionnaire. The biomarker portion of the training was conducted from 16-21 June, 2014.

The pretest participants were later used as field supervisors or editors, or as field coordinators to facilitate the data collection during the main fieldwork. Six trainers assigned by the GSS conducted the training with support from ICF International. The participants actively discussed the questionnaires and made suggestions to modify all versions. Field practice took place over four days in both rural and urban locations. Interviewers and health technicians were divided into five teams (two female interviewers, one male interviewer, and one health technician). During the pretest field practice, a total of 88 households, 77 women, and 34 men, were interviewed in English, Akan, Ewe, and Ga. Following field practice, a debriefing session was held with the pretest field staff, and modifications to the questionnaires were made based on lessons drawn from the exercise.

1.9 TRAINING OF FIELD STAFF

Training of the field staff took place over four weeks (4-30 August 2014) with 139 field data collectors (67 women and 72 men) and 55 health technicians (26 women and 29 men). Training was conducted at the Winneba Windy Lodge Hotel in the Central Region about 65 kilometres from Accra.

During the first week, all trainees were instructed in standard DHS procedures, including general interviewing techniques, conducting interviews at the household level, and measuring blood pressures. During the second week, health technicians began separate biomarker training while the other field staff (data collectors) continued to train on the Woman's and the Man's questionnaires, including a detailed review of each question and mock interviews between participants in the classroom. To provide the health technicians with practical experience measuring anthropometry among children, representatives from UNICEF and GHS organised a standardisation exercise with the health technicians. Measurements from health technicians were compared to a reference measure, which helped health technicians correct and improve on their measurement techniques whenever applicable.

All trainees were also given an overview of the 2014 GDHS biomarker collection protocol that summarised eligibility for each biomarker, appropriate procedures for obtaining informed consent, and sample transportation logistics. In addition, nine data entry personnel (seven women and two men) attended the first two weeks of questionnaire training, so that they would be familiar with the survey instruments at a later stage when they received and entered data from the completed questionnaires. During the final week, ICF staff trained field editors in the computer assisted field editing (CAFE) system. Field supervisors were trained in the collection of global positioning system (GPS) data using the Garmin eTrex10 model.

Practice interviews with real respondents took place over a course of three days (24-26 August 2014) in areas outside the 2014 GDHS sample points.

Participants were evaluated through homework, in-class exercises, quizzes, and observations made during field practice. After training, they were assigned to 25 teams composed of one supervisor, one field editor, two female interviewers, one male interviewer, and two health technicians. Fourteen interviewers and five health technicians were selected as reserve staff.

1.10 FIELDWORK

Data collection was carried out by the 25 field teams from early September to mid-December 2014. Senior staff members from the Ghana Statistical Service and the Ghana Health Service coordinated and monitored the fieldwork. Paper questionnaires were used to conduct the interviews. After the interviews, field editors entered the questionnaire data into laptops, using passwords to protect the files. Electronic data files were transferred to the central office every few days via the secured Internet File Streaming System (IFSS). Fieldwork monitoring was carried out by staff of GSS, GHS, and two survey technical specialists from The DHS Program. Data collection took 3.5 months.

1.11 DATA PROCESSING

The data processing operation included 100 percent verification (also called second data entry) and secondary editing, which involved resolution of computer-identified inconsistencies. The data processing activities at the central office were led by one key GSS officer who took part in the main fieldwork training. Data processing was accomplished using CSPro software. Data entry and editing were initiated in September 2014 and completed in February 2015.

1.12 RESPONSE RATES

Table 1.2 shows response rates for the 2014 GDHS. A total of 12,831 households were selected for the sample, of which 12,010 were occupied. Of the occupied households, 11,835 were successfully interviewed, yielding a response rate of 99 percent, the same as the 2008 GDHS household response rate (GSS, GHS, and ICF Macro 2009).

In the interviewed households, 9,656 eligible women were identified for individual interviews; interviews were completed with 9,396 women, yielding a response rate of 97 percent. In the subsample of households selected for the male survey, 4,609 eligible men were

Table 1.2 Results of the household and individual interviews

Number of households, number of interviews, and response rates, according to residence (unweighted), Ghana 2014

	Residence		
Result	Urban	Rural	Total
Household interviews			
Households selected	6,492	6,339	12,831
Households occupied	6,070	5,940	12,010
Households interviewed	5,939	5,896	11,835
Household response rate[1]	97.8	99.3	98.5
Interviews with women age 15-49			
Number of eligible women	4,753	4,903	9,656
Number of eligible women interviewed	4,602	4,794	9,396
Eligible women response rate[2]	96.8	97.8	97.3
Interviews with men age 15-59			
Number of eligible men	2,189	2,420	4,609
Number of eligible men interviewed	2,050	2,338	4,388
Eligible men response rate[2]	93.7	96.6	95.2

[1] Households interviewed/households occupied
[2] Respondents interviewed/eligible respondents

identified and 4,388 were successfully interviewed, yielding a response rate of 95 percent. The lower response rate for men was likely due to their more frequent and longer absences from the household.

HOUSING CHARACTERISTICS AND HOUSEHOLD POPULATION

2

Key Findings:

- Six in 10 households in Ghana have access to an improved source of drinking water, including a piped source within the dwelling, yard, or plot; a public tap, standpipe, tube well, or borehole; a hand pump, protected well, or protected spring; and rainwater. Three in 10 households use bottled or sachet water.
- Only 14 percent of households have an improved toilet facility that is not shared with other households.
- Seventy-eight percent of households have electricity.
- More than 7 in 10 of residents in Northern and Upper East regions and 6 in 10 residents in Upper West region are in the lowest wealth quintile.
- Forty-two percent of the population in Ghana is under age 15.
- Thirty-four percent of households are headed by women.
- Seventy-one percent of children under 5 had their births registered.
- Among households in which the place for hand washing was observed, 37 percent of households have no water, soap, or other cleansing agent for hand washing
- Twenty-six percent of females and 18 percent of males age 6 and older have no education.

This chapter provides an overview of demographic and socioeconomic characteristics of the household population, including information on housing facilities and characteristics, household assets, wealth status, and education. These data serve as a basis for understanding the socioeconomic status of households. The chapter also presents information on birth registration, children's living arrangements and orphanhood, and children's educational attainment, helping to provide an understanding of the general social environment in which children live.

In the 2014 GDHS, a household is defined as a person or group of related and unrelated persons who usually live together in the same dwelling unit(s) or in connected premises, who acknowledge one adult member as the head of the household, and who have common cooking and eating arrangements.

Information was collected from all usual members of a selected household (de jure population) as well as persons who had stayed in the selected household the night before the interview (de facto population). The difference between these two populations is very small, so all tables in this report refer to the de facto population unless otherwise specified to maintain comparability with other DHS reports.

2.1 HOUSEHOLD CHARACTERISTICS

Access to basic utilities, sources of drinking water, and water treatment practices; access to sanitation facilities, housing structure; crowdedness of dwelling spaces; and type of fuel used for cooking are physical characteristics of a household that are used to assess the general well-being and socioeconomic status of household members. Millennium Development Goal 7 (MDG 7), which focuses on environmental sustainability, is measured according to the percentage of the population using solid fuels, those with sustainable access to an improved water source, and the proportion with access to improved sanitation. This section provides information from the 2014 GDHS on household drinking water, household sanitation facilities, hand-washing practices, housing characteristics, and availability of basic amenities and utilities.

2.1.1 Water and Sanitation

The basic determinants of better health, such as access to safe water and sanitation, are still a basic problem in Ghana. Limited access to safe drinking water and sanitation facilities and poor hygiene are associated with skin diseases, acute respiratory infections (ARIs), and diarrhoeal diseases, the leading preventable diseases. The source of drinking water is important because potentially fatal diseases, such as diarrhoeal diseases, guinea worm, typhoid, cholera, schistosomiasis, trachoma, and dysentery, are water-related diseases.

Table 2.1 shows the percent distribution of the households and the de jure population by source of drinking water, time to obtain drinking water, and treatment of drinking water, according to background characteristics. The source of drinking water is an indicator of its suitability for drinking. Lack of ready access to a water source may limit the quantity of suitable drinking water that is available to a household. Even if the water is obtained from an improved source, it may be contaminated during transport or storage if fetched from a source not immediately accessible to the household. Six in ten households in Ghana (60 percent) obtain drinking water from an improved source, including a piped source within the dwelling, yard, or plot; a public tap, standpipe, tube well, or borehole; a hand pump, protected well, or protected spring; and rainwater. An additional 30 percent of households use bottled or sachet water.[1] Ten percent of households still rely on unimproved sources.

The most common source of drinking water in urban areas is sachet water (43 percent), followed by public tap or standpipe (23 percent). In rural households, the most common source for drinking water is tube well or borehole (41 percent), followed by public tap or standpipe (19 percent). The most notable change in access to drinking water sources between 2008 and 2014 is the increase in the proportion of households using sachet water from 8 percent to 29 percent in the past six years. On the other hand, the proportion of households that use drinking water from public tap/standpipe or tube well/borehole has decreased from 57 percent in the 2008 GDHS to 44 percent in the 2014 GDHS, most likely due to switching to sachet water in the latter survey.

Fifteen percent of households have water on their premises, a decline from 23 percent reported in the 2008 GDHS. This is mostly due to the decline in the percentage of households in urban areas with water on their premises, from 42 percent in 2008 to 22 percent in 2014. However, there is a substantial increase in the proportion of urban households that spend less than 30 minutes to obtain water, from 51 percent in 2008 to 71 percent in 2014. Overall, 70 percent of households in 2014 spend less than 30 minutes to obtain their drinking water, with no major differences between urban and rural households. Fifteen percent of households spend 30 minutes or longer to obtain their drinking water, 25 percent in rural areas compared with only 7 percent in urban areas.

The majority of households (93 percent) do not treat their drinking water, with similar proportions by residence. Boiling the water and straining it through cloth are the most common drinking water treatment methods (2 percent each). One percent of households are engaged in harmful practice of using camphor balls or naphthalene to purify their drinking water. Camphor or naphthalene are toxic and should not be used to treat drinking water. Overall, only 4 percent of households using an appropriate water treatment method. Over half of the households store their drinking water in a plastic container or a bucket (55 percent), 29 percent in a bottle or a sachet, 11 percent in a pot or earthenware vessel, and 6 percent in a metal container (data not shown).

---

[1] The WHO-UNICEF Joint Monitoring Program for Water Supply and Sanitation (JMP) classifies bottled/sachet water used for drinking according to the source of water that households use for cooking and handwashing (secondary source). Where information about the secondary water source is not collected, JMP does not currently categorise bottled/sachet water as an improved drinking water source (WHO and UNICEF 2014). Since the 2014 Ghana DHS did not collect information on the secondary water source, the quality of bottled/sachet water is not known. However, to ensure consistency with the 2008 GDHS findings and in accordance with the The DHS Program tabulation plan, which categorises bottled/sachet water as improved, an additional category is included in Table 2.1 to show the percentage of households/population using "improved source, including bottled/sachet water".

Table 2.1 Household drinking water

Percent distribution of households and de jure population by source of drinking water, time to obtain drinking water, and treatment of drinking water, according to residence, Ghana 2014

Characteristic	Households			Population		
	Urban	Rural	Total	Urban	Rural	Total
Source of drinking water

Number	6,503	5,332	11,835	20,432	20,791	41,223

Note: Totals may not add up to 100 percent because households with missing information are not shown separately.
[1] Since the 2014 Ghana DHS did not collect information on the secondary source of water, the quality of bottled/sachet water is not known. However, to ensure consistency with the 2008 GDHS findings and in accordance with the The DHS Program tabulation plan, which categorises bottled/sachet water as improved, an additional category is included to show the percentage of households/population using "improved source, including bottled/sachet water".
[2] Respondents may report multiple treatment methods, so the sum of treatments may exceed 100 percent.
[3] Appropriate water treatment methods include boiling, bleaching, filtering, solar disinfection, and purification tablets.

A household is classified as having an improved toilet if the toilet is used only by members of one household (i.e., it is not shared) and if the facility used by the household separates waste from human contact (WHO and UNICEF 2014). The types of facilities considered improved are toilets that flush or pour flush into a piped sewer system, septic tank, or pit latrine; ventilated improved pit (VIP) latrines; and pit latrines with a slab (Table 2.2).

Table 2.2 shows that only 14 percent of households in Ghana use improved toilet facilities that are not shared with other households, and 61 percent use facilities that would be considered improved if they were not shared. Twice as many households in urban as in rural areas have improved toilet facilities that are not shared (18 percent versus 9 percent). More than one in four (26 percent) of households use a nonimproved toilet facility, 14 percent in urban areas and 41 percent in rural areas.

Seventeen percent of households in Ghana have no toilet facility and still use the bush or open field for defecation. As expected, rural households are much more likely to have no toilet facilities than urban households (29 percent versus 7 percent).

Table 2.2 further indicates that 4 in 10 households have a toilet facility in their dwelling, yard, or plot, 51 percent in urban areas compared with 27 percent in rural areas. About one-third of households (32 percent) take less than 30 minutes to reach a toilet facility, and 1 in 10 (11 percent) take more than 30 minutes to reach a toilet facility.

Table 2.2 Household sanitation facilities

Percent distribution of households and de jure population by type of toilet/latrine facilities, according to residence, Ghana 2014

Type of toilet/latrine facility	Households			Population		
	Urban	Rural	Total	Urban	Rural	Total
Improved, not shared facility	**17.8**	**8.5**	**13.6**	**20.5**	**9.6**	**15.0**

Time to reach facility						
No facility/bush/field	7.1	28.8	16.9	7.9	34.0	21.0
In own dwelling/yard/ plot	51.3	26.5	40.1	51.5	24.3	37.8
Less than 30 minutes	30.3	35.1	32.4	29.4	32.7	31.1
More than 30 minutes	11.2	9.6	10.5	11.0	9.0	10.0
Total	100.0	100.0	100.0	100.0	100.0	100.0
Number	6,503	5,332	11,835	20,432	20,791	41,223

Note: Totals may not add up to 100 percent because households with missing information are not shown separately.
[1] Facilities that would be considered improved if they were not shared by two or more households.

2.1.2 Housing Characteristics

Housing characteristics and household assets can be used as a measure of the socioeconomic status of household members. Cooking practices and cooking fuels also affect the health of family members and the environment. For example, the use of biomass fuels exposes household members to indoor pollution, which has a direct bearing on their health and surroundings.

Table 2.3 presents information on the availability of electricity, type of flooring material, number of rooms for sleeping, type of fuel used for cooking, and place where cooking is done. Overall, 78 percent of households in Ghana have access to electricity, 91 percent in urban areas and 63 percent in rural areas. This shows a marked improvement since the 2008 GDHS, when 61 percent of households had access to electricity; the sharpest increase has occurred in rural areas (from 38 percent to 63 percent). This increase is partially attributed to the rural electrification programmes implemented by successive governments in recent years.

Among flooring materials, cement is the most common (63 percent), with rural households being more likely than urban households to have cement flooring (70 percent versus 57 percent). Other common flooring materials include linoleum or rubber carpet (12 percent) and woolen or synthetic carpets (11 percent).

Table 2.3 Household characteristics

Percent distribution of households by housing characteristics, percentage using solid fuel for cooking, and percent distribution by frequency of smoking in the home, according to residence, Ghana 2014

Housing characteristic	Residence

The number of rooms used for sleeping indicates the extent of crowding in households. Overcrowding increases the risk of contracting infectious diseases such as acute respiratory infections and skin diseases, which particularly affect children and the elderly population. Six in 10 households (61 percent) report using one room for sleeping, one in four (25 percent) use two rooms for sleeping, and 14

percent use three or more rooms. The proportion of households that uses one room for sleeping is higher in urban than in rural areas (65 percent versus 57 percent).

The presence and extent of indoor pollution depend on cooking practices, places used for cooking, and types of fuel used. According to the 2014 GDHS, 35 percent of households cook inside the house, 37 percent cook outdoors, and 24 percent cook in a separate building. The percentage of households that cook inside the dwelling is substantially higher in urban than in rural areas (48 percent versus 20 percent). By contrast, 34 percent and 43 percent of rural households cook in a separate building or outdoors, as compared with 16 percent and 31 percent, respectively, of urban households.

Table 2.3 also presents information on fuel and oil used for cooking by the Ghanaian households. Wood (37 percent), charcoal (33 percent), and liquid petroleum gas (LPG), natural gas, or biogas (24 percent) are the most commonly used cooking fuels. Urban households are much more likely than rural households to use LPG, natural gas, or biogas (37 percent versus 9 percent) or charcoal (42 percent versus 21 percent). On the other hand, a notably higher proportion of rural households use wood for cooking compared with urban households (66 percent versus 13 percent). Overall, 70 percent of households use solid fuel for cooking, i.e., charcoal, wood, straw, shrubs, grass and agricultural crops, and animal dung, a decline from 83 percent reported in the 2008 GDHS.

Red palm oil is the most commonly used cooking oil (47 percent), with a substantially higher percentage of rural households using it when compared with urban households (58 percent versus 39 percent). One-third of households use Frytol or fortified vegetable oil for cooking. Urban households are more than twice as likely as rural households to use Frytol or fortified vegetable oil (44 percent compared with 19 percent). Other vegetable oil and shear butter are each used by 7 percent of households.

A major concern for the government of Ghana is the effect of secondhand smoke, especially on the vulnerable groups, such as pregnant women, infants, and young children. The 2014 GDHS collected information on the frequency of smoking in the home in order to assess exposure of household members to secondhand smoking. Data show that 9 percent of households are exposed daily to secondhand smoke, with rural households being slightly more likely to be exposed than urban households (11 percent compared with 8 percent).

2.1.3 Household Possessions

Possession of durable consumer goods is another useful indicator of household socioeconomic status. The possession and use of household durable goods have multiple effects and implications. For instance, having access to a radio or television exposes household members to updated daily news events, information, and educational materials. Similarly, a refrigerator prolongs food storage and keeps food fresh and hygienic. A means of transportation allows greater access to services away from the local area and enhances social and economic activities. The 2014 GDHS collected information on possession of durable assets, means of transportation, and ownership of agricultural land and farm animals.

Table 2.4 shows that radios (69 percent), color televisions (62 percent), and mobile telephones (85 percent) are common durable goods owned by households in Ghana. Refrigerators are owned by 35 percent of households. Ownership of each of these household items is higher in urban than in rural areas. Possession of color televisions, mobile phones, and refrigerators has increased since the 2008 GDHS survey, while possession of radios has decreased slightly. It is noteworthy that there has been an especially sharp increase in mobile phone ownership in Ghana, from 57 percent in 2008 to 85 percent in 2014, especially in rural households where mobile phone ownership has more than doubled (from 37 percent to 76 percent). In addition, 42 percent of households own a video deck or DVD/VCD and 16 percent have a sewing machine. Computers and access to the internet was reported each by 14 percent of households (data not shown).

Looking at means of transport, bicycles continue to be common, with 23 percent of households owning a bicycle, 17 percent in urban areas and 31 percent in rural areas. Ownership of a motorcycle is more common in rural areas (11 percent) than in urban areas (7 percent), while ownership of a car or truck is more common in urban than in rural areas (13 percent compared with 4 percent).

Ghana is predominantly an agricultural economy, with a large proportion of the population engaged in this sector. The 2014 GDHS data indicate that 39 percent of households own agricultural land, with rural households notably more likely to own land (59 percent) than urban households (22 percent). Thirty-six percent of households in the country possess farm animals, 55 percent in rural areas as compared with 20 percent in urban areas.

2.2   SOCIOECONOMIC STATUS INDEX

The wealth index has been used in many DHS reports to measure inequalities in household characteristics, in the use of health and other services, and in health outcomes. It is an indicator of wealth that is consistent with expenditure and income measurement among households. The index was constructed from household asset data using principal components analysis. These assets or consumer items consist of a television, bicycle, or car, as well as dwelling characteristics, such as a source of drinking water, sanitation facilities, and type of flooring material.

In its current form, which takes better account of urban-rural differences in scores and indicators of wealth, the wealth index is created in three steps. In the first step, a subset of indicators common to urban and rural areas is used to create wealth scores for households in both areas. Categorical variables to be used are transformed into separate dichotomous (0-1) indicators. These indicators and those that are continuous are then examined using a principal components analysis to produce a common factor score for each household. In the second step, separate factor scores are produced for households in urban and rural areas using area-specific indicators. The third step combines the separate area-specific factor scores to produce a nationally applicable combined wealth index by adjusting area-specific scores through a regression on the common factor scores. This three-step procedure permits greater adaptability of the wealth index in both urban and rural areas. The resulting combined wealth index has a mean of zero and a standard deviation of one. Once the index is computed, national-level wealth quintiles (from lowest to highest) are obtained by assigning the household score to each de jure household member, ranking each person in the population by his or her score, and then dividing the ranking into five equal categories, each

comprising 20 percent of the population. The 2014 GDHS provides an opportunity to examine the distribution of Ghana's population by household wealth status.

Table 2.5 presents distributions across the five wealth quintiles by residence and region. These distributions indicate the degree to which wealth is evenly (or unevenly) distributed according to geographic area.

A large majority of the urban population (71 percent) is in the highest two wealth quintiles, while a much lower proportion of rural residents (10 percent) falls in this category. The majority of rural residents are in the lowest and the second wealth quintiles (36 percent and 33 percent, respectively). By contrast, only 4 percent and 7 percent, respectively, of urban residents fall in the lowest two quintiles.

By region, data show that Greater Accra is the richest region, with 52 percent of the population in the highest wealth quintile, compared with only 2 percent each of the population in the Northern and Upper East regions. More than 7 in 10 of the population in the Northern and Upper East regions (72 percent and 79 percent, respectively) and 6 in 10 of the population in the Upper West region (60 percent) is in the lowest wealth quintile.

Table 2.5 also presents information on the Gini coefficient, which indicates the level of concentration of wealth (0 being an equal distribution and 1 a totally unequal distribution). This ratio is expressed as a proportion between 0 and 1. Wealth inequality, as measured by the Gini coefficient, is higher in rural (0.25) than in urban areas (0.10). Inequality in wealth is highest in Upper West and lowest in Greater Accra (Gini coefficients of 0.33 and 0.14, respectively).

Table 2.5 Wealth quintiles

Percent distribution of the de jure population by wealth quintiles, and the Gini Coefficient, according to residence and region, Ghana 2014

2.3   HAND WASHING

Hand washing is one of the most efficient ways to stop germs from spreading and protect people from contracting communicable diseases. The practice is promoted by the Ghanaian government, various institutions, and nongovernmental organisations. There is an ongoing campaign in communities at schools and households to boost awareness of the importance of having designated places for hand washing with running water and soap.

Table 2.6 provides information on designated places for hand washing in households and the use of water and cleansing agents for washing hands according to place of residence, region, and wealth quintile. In the 2014 GDHS, interviewers were asked to observe the place where household members usually washed their hands. They also observed the regularity of water supply and whether households had

cleansing agents near the place of hand washing. Such observations were made in 53 percent of households selected for the survey.

Among the observed households, 39 percent had soap and water at the place where household members washed their hands, 19 percent had water only, 4 percent had soap but no water, and less than 1 percent had water and other cleansing agents (such as ash, mud, or sand), or only cleaning agents other than soap. Thirty-seven percent of households did not have water, soap, or other cleansing agents. In general, although the hand washing place was observed, most likely these households did not have a fixed, designated place for hand washing.

Forty-six percent of the households in urban areas had soap and water, compared with 29 percent of rural households. At the regional level, more than half of households in Greater Accra (51 percent) had soap and water, compared with less than one in five (18 percent) households in Upper West. Presence of soap and water increases steadily with wealth, from 20 percent of the poorest households to 64 percent of the richest households.

Table 2.6 Hand washing

Percentage of households in which the place most often used for washing hands was observed, and among households in which the place for hand washing was observed, percent distribution by availability of water, soap, and other cleansing agents, Ghana 2014

[1] Soap includes soap or detergent in bar, liquid, powder, or paste form. This column includes households with soap and water only as well as those that had soap and water and another cleansing agent.
[2] Cleansing agents other than soap include locally available materials such as ash, mud or sand
[3] Includes households with soap only as well as those with soap and another cleansing agent

2.4   HOUSEHOLD POPULATION BY AGE AND SEX

Table 2.7 shows the distribution of the de facto household population by age and sex according to urban and rural residence. The 2014 GDHS enumerated a total of 40,337 persons (21,035 females and 19,302 males). More than 4 in 10 of the population in Ghana (42 percent) is under age 15 (Figure 2.1), similar to 41 percent reported in the 2008 GDHS. The data show that 14 percent of the population are under age 5, a slight increase from 13 percent in 2008. Persons age 65 and older account for about 5 percent of the total population, the same as in 2008.

There is a slightly higher proportion of children under 5 in rural than in urban areas (15 percent versus 13 percent). The concentration of the population is high in the 5-9 and 10-14 age groups (14 percent and 13 percent, respectively), potentially creating pressure for schooling and adolescent care. The overall sex ratio (the number of males for every 100 females) is 92, slightly higher than the sex ratio of 91 reported in the 2008 GDHS.

Table 2.7 Household population by age, sex, and residence

Percent distribution of the de facto household population by five-year age groups, according to sex and residence, Ghana 2014

2.5 HOUSEHOLD COMPOSITION

Information on household composition is critical for understanding family size, household headship, and orphanhood and for implementing meaningful population-based policies and programmes. Household composition is also a determinant of health status and wellbeing.

Table 2.8 presents information on household composition in Ghana. Almost twice as many households are headed by men as by women (66 percent versus 34 percent), a pattern observed both in urban and in rural areas.

The average household size in 2014 is 3.5 persons, compared with 3.7 in 2008. The household size is somewhat larger in rural areas (mean size of 3.9 persons) when compared with urban areas (mean size of 3.1 persons). Single-person households are more common in urban areas (29 percent) than in rural areas (22 percent), perhaps due to the influx of unmarried young individuals migrating to urban areas in search of employment or to further their education.

Table 2.8 Household composition

Percent distribution of households by sex of head of household and by household size; mean size of household, and percentage of households with orphans and foster children under 18 years of age, according to residence, Ghana 2014

Characteristic	Residence		Total
	Urban	Rural

Percentage of households with orphans and foster children under 18 years of age			
Foster children[1]	15.5	16.6	16.0
Double orphans	1.0	1.0	1.0
Single orphans[2]	5.9	7.7	6.7
Foster and/or orphan children	18.4	20.5	19.4
Number of households	6,503	5,332	11,835

Note: Table is based on de jure household members, i.e., usual residents.
[1] Foster children are those under age 18 living in households with neither their mother nor their father present.
[2] Includes children with one dead parent and an unknown survival status of the other parent.

The 2014 GDHS also collected information on the presence of foster children and orphans in households. Foster children are children under age 18 living in households with neither their mother nor their father present; orphans are children with one (single orphans) or both parents (double orphans) dead. Foster children and orphans are of concern because they may be at greater risk of neglect, maltreatment or exploitation with their mothers or fathers not present to assist them. Sixteen percent of all households in Ghana have foster children, 16 percent in urban households and 17 percent in rural households. Single orphans are present in 7 percent of the households, whereas double orphans are present in 1 percent of households.

Overall, 19 percent of households have foster and/or orphan children, a decrease from 22 percent in the 2008 GDHS.

2.6 BIRTH REGISTRATION

Although Ghana has a legal and administrative structure stipulating official registration of births according to standard procedures, only 6 out of 10 births are registered annually. The practice of formally registering births is not widely adhered to in the country, even though the registration system was implemented over 100 years ago. Despite the existence of compulsory nationwide registration laws in the country, registration centres are highly inadequate and poorly equipped, especially in the rural areas, due to a number of reasons, the predominant one being inadequate financial resources (UNICEF 2013).

The Births and Deaths Registry Act 301 of 1965 requires the issuance of a birth certificate immediately after birth, free of charge. Until mid-2003, the legal period for free birth registration of infants was within 21 days of birth. However, since mid-2013, the period has been extended to 12 months, in order to encourage early registration of all births by parents or caretakers (Government of Ghana 1965).

Birth registration information was solicited for all children age 0-4 years. Table 2.9 presents the percentage of the de jure population under age 5 whose births are registered with the civil authorities, according to background characteristics. About 7 in 10 children under age 5 (71 percent) have their births registered: 56 percent are registered and have a birth certificate, while 15 percent are registered but do not have a birth certificate.

Children under age 2 (66 percent) are less likely to be registered than children age 2-4 (74 percent). Although not legally required, the registration of older children may be primarily due to the practice of asking for a child's birth certificate for school admission.

Table 2.9 Birth registration of children under age 5

Percentage of de jure children under age 5 whose births are registered with the civil authorities, according to background characteristics, Ghana 2014

| Background characteristic | Children whose births are registered | | | |
	Percentage who had a birth certificate	Percentage who did not have a birth certificate	Percentage registered	Number of children

Fourth	69.3	11.7	81.1	1,095
Highest	79.9	8.1	88.0	1,042
Total	55.8	14.7	70.5	5,819

Children in urban areas (79 percent) are notably more likely to be registered than those in rural areas (63 percent). At the regional level, only half of births in Volta are registered, as compared with more than 8 in 10 births registered in the Central and Ashanti regions (81 percent and 82 percent, respectively).

Birth registration increases with wealth, from 58 percent among children in the poorest households to 88 percent among children in the richest households.

2.7 CHILDREN'S LIVING ARRANGEMENTS, ORPHANHOOD, AND SCHOOL ATTENDANCE

The 2014 GDHS collected information on living arrangements of children and orphanhood. Living arrangements should be monitored together with the proportion of foster and orphan children because of their significant effects on the comprehensive development of children.

Table 2.10 shows the percent distribution of children under age 18 by their living arrangements and survivorship of parents. Of the 19,074 children under age 18 reported in the 2014 GDHS, 55 percent live with both parents, 21 percent live with their mother only, although their father is alive, 4 percent live with their father only, although their mother is alive, and 13 percent live with neither of their natural or biological parents, although both parents are alive.

Table 2.10 Children's living arrangements and orphanhood

Percent distribution of de jure children under 18 years of age by living arrangements and survival status of parents, the percentage of children not living with a biological parent, and the percentage of children with one or both parents dead, according to background characteristics, Ghana 2014

Background characteristic	Living with both parents	Living with mother but not with father		Living with father but not with mother		Not living with either parent					Total	Percentage not living with a biological parent	Percentage with one or both parents dead[1]	Number of children

Note: Table is based on de jure members, i.e., usual residents.
[1] Includes children with father dead, mother dead, both dead, and one parent dead but missing information on survival status of the other parent.

Table 2.10 also provides information on the extent of orphanhood, that is, the proportion of children who have lost one or both parents. Less than 1 percent of children under age 18 have both parents dead and 8 percent have one or both parents dead. The percentage of children living with both biological parents decreases with increasing age of the child. This may be due to children moving to a relative's house to pursue further education or seek work. Children in rural areas are more likely than those in urban areas to live with both parents (60 percent versus 49 percent). The Northern region (78 percent) has the highest proportion of children living with both parents and the Eastern region has the lowest proportion (45 percent).

By wealth status, the proportion of children under age 18 living with both parents shows a U-shaped pattern with increasing wealth quintile. The highest proportions are among children in the lowest and highest wealth quintiles (69 percent and 57 percent, respectively) and the lowest proportion is in the middle wealth quintile (44 percent).

In the 2014 GDHS, eligible women were asked if they had any sons or daughters to whom they had given birth, who were still alive, but who did not live with their mother at the time of the survey. For each identified child under age 18 who did not live with the mother, the respondent was asked where and with whom the children lived at the time of the interview. The findings are shown in Figure 2.2.

The majority of female and male children under age 18 who did not live with their mother at home at the time of the survey were living with relatives (90 percent). Six percent of females and 5 percent of males were living in boarding schools, and 4 percent and 3 percent, respectively, were living with family or friends.

**Figure 2.2 Children under age 18 living away from home:
Place or person with whom they currently live**
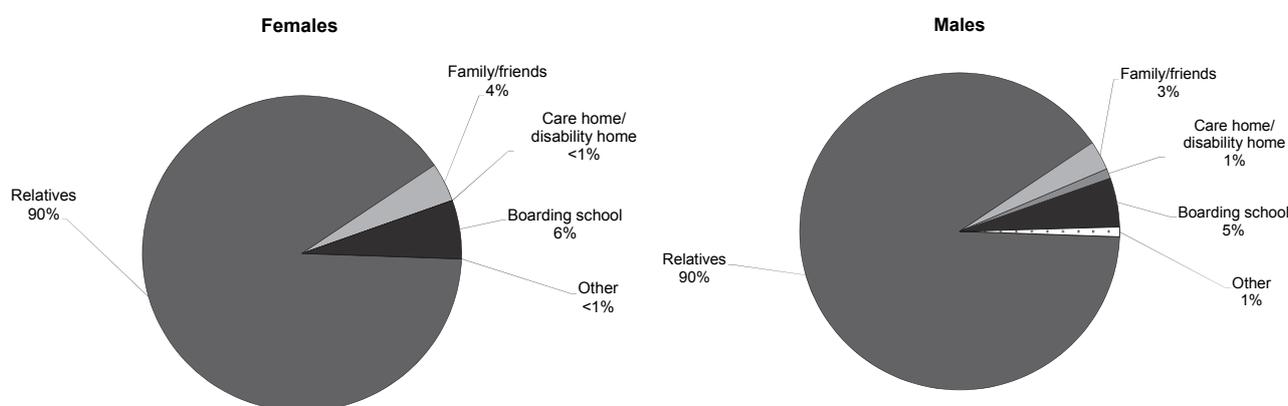

Children orphaned or vulnerable by death or acute illness of one or both parents may or may not go to school. Often, these children are compelled to work to pay their school fees or eventually drop out to assist in family businesses. The 2014 GDHS collected information on school attendance of children age 10-14 by parental survival. The findings are presented in Table 2.11. Seventy-six percent of children age 10-14 whose both parents are deceased are attending school, an increase from 67 percent in 2008. Among children age 10-14 whose parents are both alive and who live with at least one parent, 81 percent are attending school, compared with 88 percent in 2008. The overall ratio of school attendance of children whose parents are dead to those whose parents are living (when the child resides with at least one parent) is 0.94. Further breakdown by background characteristics is not possible due to the small number of orphans (95 unweighted cases).

Table 2.11 School attendance by survivorship of parents

For de jure children age 10-14 , the percentage attending school by parental survival and the ratio of the percentage attending, by parental survival, according to background characteristics, Ghana 2014

Note: Table is based only on children who usually live in the household. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] Ratio of the percentage with both parents deceased to the percentage with both parents alive and living with a parent

2.8   EDUCATION OF HOUSEHOLD POPULATION

Studies have shown that education is one of the major socioeconomic factors to influence a person's behaviour and attitude. In general, the higher the level of education of a woman, the more knowledgeable she is about the use of health facilities, family planning methods, and the health of her children.

Education in Ghana has undergone several changes in recent years (see Chapter 1). Pre-school education has been incorporated into basic education, and all primary schools are required to have nurseries or kindergartens. The basic education is free and compulsory, with the goal of providing educational attainment for all. The Ghana Education Trust Fund (GETFUND), set up in 2000, has resulted in major improvements in the educational infrastructure to support the country's tertiary institutions.

The current educational system is based on a three-tier system: six years of primary education, followed by three years of junior high school (JHS), formerly called junior secondary school (JSS), and a further three years at the senior high school (SHS) level. At the secondary level, in the 2007/2008 academic year, the three-year Senior Secondary School (SSS) system was changed to the four-year Senior High School, but this policy was reversed in 2009.

2.8.1   Educational Attainment of Household Population

Tables 2.12.1 and 2.12.2 show the percent distribution of the de facto female and male household population age 6 and older by level of education and background characteristics.

Table 2.12.1 shows that 26 percent of the female household population has never been to school, a decline from 31 percent in 2008. Among females age 6 and older, 27 percent have some primary education, 5 percent have completed primary school only, 39 percent have some secondary education or have completed secondary school, and 4 percent have more than a secondary school education.

The data show that the proportion of females with no education is higher in the older ages, suggesting some improvement in education over the years. This may be due to the impact of the Free Compulsory Universal Basic Education (FCUBE) programme, which was introduced in 1996. Educational attainment varies by place of residence. Urban females are more likely to be educated than their rural counterparts. For instance, 18 percent of urban females have no education, compared with 35 percent of rural females. The proportion of urban females with some secondary education or higher (54 percent) is notably higher than that of their rural counterparts (30 percent).

Table 2.12.1 Educational attainment of the female household population

Percent distribution of the de facto female household population age 6 and over by highest level of schooling attended or completed and median years completed, according to background characteristics, Ghana 2014

[1] Completed 6th grade at the primary level
[2] Completed 6th grade at the secondary level

Findings show that females in the northern half of the country are disadvantaged. The percentage of females who have never been to school is high in Northern (59 percent), followed by Upper West (53 percent) and Upper East (45 percent), as compared with only 14 percent of females in Greater Accra. On the other hand, 20 percent of females in Greater Accra have completed secondary education or higher, compared with 4 percent or less each in the Northern, Upper East, and Upper West regions.

The proportion of female household members who have never attended school decreases sharply with increasing wealth, from 52 percent in the lowest quintile to 8 percent in the highest quintile. Overall, the median number of completed years of schooling among females age 6 and older is 4.4.

Table 2.12.2 shows that 18 percent of males have never been to school, a decline from 22 percent in 2008. Thirty-one percent of males have had some primary education or have completed primary education, 44 percent have had some secondary or have completed secondary education, and 8 percent have more than a secondary education.

Similar to females, the proportion of males with no education is higher in the older ages. Twenty-five percent of males in rural areas have no education, compared with 10 percent in urban areas. There is a marked urban-rural differential in secondary and higher education: 23 percent of males in urban areas have completed secondary or higher education, compared with 9 percent in rural areas.

Across the regions, the pattern for males is similar to that observed for females. Higher proportions of males in the three northern regions (Northern, 44 percent; Upper West, 41 percent; and Upper East, 32 percent) have never been to school, compared with 20 percent or less of males in other regions. The percentage of males with no education is strongly associated with wealth; those in the lowest quintile are the most likely to have no education (38 percent), compared with only 5 percent of males in the richest households.

The median number of completed years of schooling among the male household population age 6 and older is 5.9.

Table 2.12.2 Educational attainment of the male household population

Percent distribution of the de facto male household population age 6 and over by highest level of schooling attended or completed and median years completed, according to background characteristics, Ghana 2014

2.8.2 School Attendance Ratios

The 2014 GDHS collected information on school attendance for the population age 3-24 that allows the calculation of net attendance ratios (NARs) and gross attendance ratios (GARs). The NAR for primary school is the percentage of the primary-school-age (6-11 years) population that is attending primary school. The NAR for secondary school is the measure of the secondary-school-age (12-17 years) population that is attending secondary school. By definition, the NAR cannot exceed 100 percent. The GAR however, measures participation at each level of schooling among persons age 6-25. The GAR is almost always higher than the NAR for the same level because the GAR includes participation by those who may be older, because they may have started school late, may have repeated one or more grades in school, or may have dropped out of school and later returned, or may be younger than the official age range for that level.

Table 2.13 presents data on the NAR and GAR for the de facto household population by level of schooling and sex, according to place of residence, region, and wealth quintile. Seventy percent of children age 6-11 who should be attending primary school are currently doing so, a slight decrease from 74 percent in 2008. The GAR at the primary school level is 99 percent. The distribution shows that both the NAR and the GAR are much lower at the secondary school level: 39 percent of students age 12-17 who should be attending secondary school are in school (NAR), a slight decrease from 42 percent in 2008. The GAR for secondary school is 50 percent.

The results show no differences in the primary or secondary school NARs between males and females, indicating no notable gender gap in school attendance for the Ghanaian school-age population who should be attending school at a given level. However, the GAR at the secondary school level is slightly higher for males than for females (53 percent versus 47 percent).

The NAR at both the primary and secondary levels are lower in rural than in urban areas. For instance, the NAR at the primary school level is 66 percent in rural areas compared with 74 percent in urban areas. Similarly, the NAR at the secondary school level is 32 percent in rural areas, compared with 46 percent in urban areas. Regional differences are also pronounced. The primary school NAR is lowest in the Upper West region (64 percent) and the secondary school NAR is lowest in the Northern, Upper East, and Upper West regions (30 percent each). The GAR at the secondary school level is also higher in urban areas. However, there is almost no urban-rural difference in the GAR at the primary school level. The GAR at the primary school level is highest in the Upper East region, indicating higher overage or underage attendance than in other regions. The lowest GAR at the secondary level is in Central region (31 percent) and the highest is in Volta (58 percent).

There is a strong relationship between household economic status and school attendance at both the primary and secondary levels and among both males and females. For example, the primary school NAR increases from 61-64 percent among students from households in the lowest two wealth quintiles to 81 percent among students from the richest households. Similarly, the NAR for secondary school rises from 25 percent among students in the lowest wealth quintile to 50-54 percent among those in the top two wealth quintiles.

Table 2.13 also shows the Gender Parity Index (GPI), which represents the ratio of the NAR and GAR for females to the NAR and GAR for males. It is a more precise indicator of gender differences in the schooling system. A GPI less than 1 indicates that a smaller proportion of females than males attend school. In Ghana, the GPI is 1.00 for primary school attendance and 1.01 for secondary school attendance, indicating no gender gaps. There are no notable differences in the primary school GPI for NAR by background characteristics. At the secondary school level, the widest gender gap in attendance is in Northern region (GPI of 0.88) and among the richest households (GPI of 0.84). The indexes for GAR at the primary and secondary levels are slightly less than 1 (0.98 for primary school and 0.89 for secondary

school), indicating some gender gap, especially at the secondary school level. The gender gap in attendance has remained unchanged over the last six years at the primary and secondary levels.

Table 2.13 School attendance ratios

Net attendance ratios (NAR) and gross attendance ratios (GAR) for the de facto household population by sex and level of schooling; and the Gender Parity Index (GPI), according to background characteristics, Ghana 2014

[1] The NAR for primary school is the percentage of the primary-school age (6-11 years) population that is attending primary school. The NAR for secondary school is the percentage of the secondary-school age (12-17 years) population that is attending secondary school. By definition the NAR cannot exceed 100 percent.
[2] The GAR for primary school is the total number of primary school students, expressed as a percentage of the official primary-school-age population. The GAR for secondary school is the total number of secondary school students, expressed as a percentage of the official secondary-school-age population. If there are significant numbers of overage and underage students at a given level of schooling, the GAR can exceed 100 percent.
[3] The Gender Parity Index for primary school is the ratio of the primary school NAR (GAR) for females to the NAR (GAR) for males. The Gender Parity Index for secondary school is the ratio of the secondary school NAR (GAR) for females to the NAR (GAR) for males.

Figure 2.3 shows that attendance rates increase up to ages 9-11 for both males and females, with some fluctuations for females, then they drop gradually.

Figure 2.3 **Age-specific attendance rates of the de-facto population 5 to 24 years**

Percent

GDHS 2014

CHARACTERISTICS OF RESPONDENTS

3
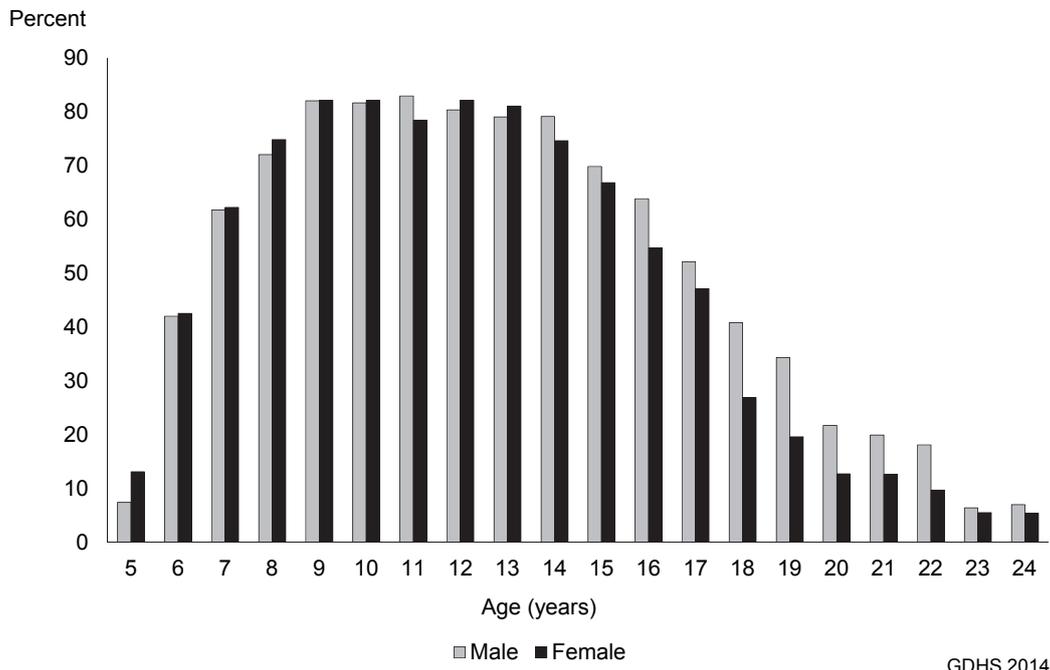

Key Findings:

- More than half of women and men age 15-49 (54 percent and 53 percent, respectively) live in urban areas, an increase from 49 percent and 46 percent, reported in the 2008 GDHS.
- Nineteen percent of women and 9 percent of men age 15-49 have never attended school; more are in school now than in 2008 when 21 percent and 13 percent did not attend.
- The median age of enrolment in primary school among women and men age 15-24 is 6.5 years.
- Large percentages of women and men age 15-24 who stopped going to school (38 percent and 39 percent, respectively) indicated they had no money to cover the education costs.
- Sixty-seven percent of women and 82 percent of men age 15-49 are literate, an increase from the 2008 literacy levels of 63 percent and 77 percent, respectively.
- Men are more likely to have access to the media than women; 13 percent of men are exposed to all three media at least once a week compared with only 5 percent of women.
- Thirty-one percent of women and 14 percent of men age 15-49 are not exposed to any media.
- Overall, 26 percent of employed women in the agricultural sector are not paid at all, mainly because they are employed by a family member. On the other hand, 14 percent of women who are employed in the nonagricultural sector are not paid for their work.

T he purpose of this chapter is to create a demographic and socioeconomic profile of individual female and male respondents in the 2014 Ghana Demographic and Health Survey (GDHS). This information helps in the interpretation of findings presented later in the report and provides an indication of the representativeness of the survey. The chapter first describes basic background characteristics, including age, religion, ethnicity, marital status, residence, and wealth status. It then provides more detailed information on education, literacy, media exposure, and employment.

Throughout this report, numbers in the tables reflect weighted numbers. Percentages based on 25 to 49 unweighted cases are shown in parentheses, and percentages based on fewer than 25 unweighted cases are suppressed and replaced with an asterisk, to caution readers when interpreting data that a percentage based on fewer than 50 cases may not be statistically reliable.[1]

3.1 CHARACTERISTICS OF SURVEY RESPONDENTS

Table 3.1 shows the weighted and unweighted numbers and the weighted percent distributions of women and men age 15-49 who were interviewed in the 2014 GDHS, by background characteristics. More than half of the respondents age 15-49 (52 percent of women and 53 percent of men) are under age 30, reflecting the young age structure of the population. The vast majority of respondents are Christian. More than 4 in 10 women (41 percent) and 3 in 10 men (32 percent) are Pentecostal/Charismatic, and 39 percent

---

[1] Parentheses are used if early childhood mortality rates are based on 250 to 499 children exposed to the risk of mortality in any of the component rates; early childhood mortality rates are suppressed if they are based on fewer than 250 children exposed to the risk of mortality in any of the component rates.

of women and 42 percent of men are Catholic, Anglican, Methodist, Presbyterian, or other Christian. Fifteen percent of women and 18 percent of men are Muslim.

Note: Education categories refer to the highest level of education attended, whether or not that level was completed.
na = Not applicable

As expected, the Akans form the largest ethnic group, with about half of respondents belonging to this group, followed by the Mole-Dagbanis, which account for 15 percent each of women and men, and the Ewes, which account for 14 percent of women and 13 percent of men.

One-third of women (33 percent) and nearly half of men (48 percent) have never been married. Women are more likely to be married or living together with a partner (i.e., in union) than men (57 percent versus 48 percent). More women than men are also divorced or separated (8 percent versus 4 percent) or widowed (3 percent versus less than 1 percent).

More than half of women (54 percent) and men (53 percent) live in urban areas, an increase from 49 percent and 46 percent, respectively, in the 2008 GDHS. By region, the largest proportion of women and men reside in Greater Accra (20 percent and 22 percent, respectively), and the smallest proportion reside in the Upper West region (2 percent each).

In general, most men and women in Ghana have some formal education. However, 19 percent of women and 9 percent of men have never attended school, a decrease from the figures of 21 percent and 13 percent, respectively, reported in the 2008 GDHS survey. Men tend to be more educated than women: 35 percent of men have a secondary or higher education, as compared with 22 percent of women.

3.2 EDUCATIONAL ATTAINMENT BY BACKGROUND CHARACTERISTICS

Education provides people with the knowledge and skills that can lead to better employment opportunities and a better quality of life. Education level is closely associated with the health of women and children as well as reproductive health behaviours of women and men.

Tables 3.2.1 and 3.2.2 show the distribution of women and men by highest level of schooling attended or completed and the median number of years of schooling, according to background characteristics. Table 3.2.1 shows that 19 percent of women age 15-49 have never been to school, 13 percent have some primary education, 5 percent have completed primary school, 46 percent have some secondary education, 11 percent have completed secondary school, and 6 percent have attained more than a secondary education.

Older women age 40-49 (32-36 percent), those who reside in rural areas (29 percent), women who live in Northern region (66 percent), and those in the poorest wealth quintile (52 percent) are most likely to have no education. The urban-rural and wealth quintile differences in education are more pronounced at the secondary and higher levels. For example, women in urban areas are more than twice as likely as those in rural areas to have completed secondary education (16 percent versus 6 percent). Similarly, 22 percent of women in the highest wealth quintile have completed secondary education, compared with just 2 percent of women in the lowest wealth quintile.

Nationally, women have completed a median of 7.8 years of schooling. Looking at age, women in the 20-24 age group have the highest median years of schooling (8.5 years) while those age 45-49 have the lowest number of median years of schooling (4.9 years). Urban women have completed a median of 8.5 years of schooling compared with 5.7 years among rural women. Median number of years completed is highest among women from Greater Accra (8.7 years) and lowest among women in the Northern region (0.0 years). There is a notable difference in median number of schooling years by wealth quintile; it is 9.6 years among women in the highest wealth quintile versus 0.0 years among those in the lowest quintile.

Table 3.2.1 Educational attainment: Women

[1] Completed 6th grade at the primary level
[2] Completed 6th grade at the secondary level

Similar patterns in educational attainment are observed among men (Table 3.2.2). Nationally, 9 percent of men age 15-49 have no education, 10 percent have some primary education, 4 percent have completed primary education, 50 percent have some secondary education, 15 percent have completed secondary education, and 12 percent have completed secondary or higher schooling.

Men age 45-49 are most likely to have no education (17 percent), while the youngest men age 15-19 are the least likely to have no education (3 percent). Urban residents have higher levels of educational attainment than their rural counterparts; only 4 percent of urban men have no education, compared with 15 percent of rural men. By contrast, 16 percent of men in urban areas have more than a secondary education, compared with 6 percent of rural men. The percentage with no education is highest among men in the Northern region (47 percent) and lowest among men in the Eastern region (2 percent). Thirty-two percent of men in the lowest wealth quintile have no schooling compared with less than 1 percent of men in the highest quintile. On the other hand, 29 percent of men in the highest wealth quintile have more than a secondary education compared with less than 1 percent of men in the lowest quintile.

At the national level, men age 15-49 have completed a median of 8.5 years of schooling. Men age 20-24 (12.2 years) and men in urban areas (9.1 years) have the highest median number of school years when compared with other age groups and with rural residents. The median number of completed years of schooling ranges from 9.5 years in Greater Accra to 2.7 years in Northern. Median years of schooling increases from 5.0 years among the poorest men to 13.3 years among the wealthiest men.

Survey results show that men have more education than women above the primary level. For example, twice as many men as women have completed more than a secondary education (12 percent compared with 6 percent).

Table 3.2.2 Educational attainment: Men

Percent distribution of men age 15-49 by highest level of schooling attended or completed, and median years completed, according to background characteristics, Ghana 2014

3.3   SCHOOL ATTENDANCE

In the 2014 Ghana DHS all respondent age 15-24 who ever attended school were asked at what age the respondent age 24 or younger started primary school and whether the respondent age 24 or younger is currently attending school at any level. If the respondent is currently not attending school, she or he was asked why the respondent is not currently attending any school.

Table 3.3.1 and Table 3.3.2 show the median age of enrollment in primary school among women and men age 15-24, respectively, who ever attended school, and percent distribution of respondents age 15-24 who ever attended school and who are not currently attending school, by reason for stopping school, according to background characteristics.

The median age for enrolment in primary school among women age 15-24 is 6.5 years. The median age for enrolment is slightly lower for women in urban than in rural areas (6.2 years versus 6.9 years). Young women in Upper East (8.1 years) and Upper West (8.0 years) and those in the lowest wealth quintile (7.9 years) have the highest median age for enrolment in primary school when compared with other sub groups.

Respondents age 15-24 who had attended school but were not attending school at the time of the survey were asked why they stopped going. About 4 in 10 women age 15-24 (38 percent) indicated they had no money to cover the education costs. Other reasons for quitting include having completed the

desired level of education (13 percent), waiting for approved admission (11 percent), having family reasons or getting married (9 percent), having bad grades (7 percent), having no desire to continue education (6 percent), having to work (5 percent), becoming pregnant and health reasons (2 percent each), and moving or changing residence (1 percent).

The percentage of women age 15-24 who reported they stopped going to school because they had no money to cover the education costs is highest among rural residents (40 percent), those living in Eastern region (45 percent), and among young women in the middle wealth quintile (44 percent).

Table 3.3.1 School attendance: Women 15-24

Median age of enrolment in primary school among women age 15-24 who ever attended school, and percent distribution of women age 15-24 who ever attended school and who are not currently attending school, by reason for stopping school, according to background characteristics, Ghana, 2014

Table 3.3.2 shows that the median age of enrolment in primary school is the same among men as it is among women age 15-24 (6.5 years). Rural residents (7.0 years), those living in Volta (8.3 years), and young men in the lowest wealth quintile (7.7 years) have the highest median age of enrollment in primary school.

As with women, almost four in ten men (39 percent) not attending school at the time of the survey indicated lack of money to cover costs as the main reason for stopping. Other reasons included having completed the desired level of education (18 percent), having to work (12 percent), waiting for approved admission (11 percent), no desire to continue education (8 percent), bad grades (3 percent), and moving or changing place of residence, health reasons, family reasons, or getting married (1 percent each).

Young men who reside in rural areas (43 percent), those who live in Volta (66 percent), and men who belong to the second wealth quintile (52 percent) are the most likely to report that they stopped going to school because of lack of money to cover costs.

Table 3.3.2 School attendance: Men 15-24

Median age of enrolment in primary school among men age 15-24 who ever attended school, and percent distribution of men age 15-24 who ever attended school and who are not currently attending school, by reason for stopping school, according to background characteristics, Ghana, 2014

Note: Figures in parentheses are based on 25-49 unweighted cases.

3.4 LITERACY

The ability to read and write is an important personal asset that empowers women and men by increasing opportunities in life. Knowing the distribution of the literate population of a country can help programme managers—especially those concerned with health and family planning—reach their targeted audiences with their messages. The 2014 GDHS assessed literacy by asking respondents to read a simple sentence in the local language (or in English). Respondents were scored on whether they could not read at all, or read part or all of the sentence shown to them. Only women and men who had never attended school and those who had primary or middle/JSS/JHS education were asked to read the sentence in the language they were most familiar with. Respondents with a secondary or higher education were assumed to be literate. Persons who were blind or visually impaired were excluded. Results are shown in Table 3.4.1 for women and in 3.4.2 for men.

Table 3.4.1 indicates that two-thirds of women in Ghana (67 percent) are literate, an increase from 63 percent in the 2008 GDHS. Literacy is much higher among the youngest women age 15-19 (85 percent), and it decreases steadily with age to 47 percent among the oldest women age 45-49, suggesting more education opportunities for the younger generation. Literacy varies by place of residence; 78 percent of women in urban areas are literate, compared with 54 percent of rural women. Regional differences with regard to literacy are notable; literacy is highest among women in the Greater Accra region (81 percent) and lowest among women in the Northern region (27 percent). By wealth, literacy ranges from 32 percent among women in the lowest wealth quintile to 91 percent among women in the highest quintile, reaffirming a positive association between economic status and literacy.

Table 3.4.1 Literacy: Women

Percent distribution of women age 15-49 by level of schooling attended and level of literacy, and percentage literate, according to background characteristics, Ghana 2014

[1] Refers to women who attended secondary school or higher and women who can read a whole sentence or part of a sentence

Table 3.4.2 shows that men have a higher literacy level than women (82 percent versus 67 percent). This is an increase from the 2008 GDHS, which reported a literacy level of 77 percent among men. Similar to women, literacy among men is highest for the 15-24 age group (89 percent). Seventy-two percent of rural men are literate, as compared with 91 percent of urban men. There are variations across regions. Greater Accra has the highest proportion of literate men (92 percent), while Northern has the lowest proportion (45 percent). Literacy increases steadily with wealth from 52 percent among the poorest men to 99 percent among men in the highest wealth quintile.

3.5   ACCESS TO MASS MEDIA

In the 2014 GDHS, exposure to media was assessed by asking respondents whether they listened to the radio, watched television, or read a newspaper or magazine at least once a week. Programme managers and planners use this information to determine which media may be most effective for disseminating health-related information to targeted audiences. Tables 3.5.1 and 3.5.2 show exposure to specific media on a weekly basis, by background characteristics, for women and men.

The data show that 52 percent of women and 78 percent of men age 15-49 listen to the radio at least once a week, and 51 percent of women and 66 percent of men watch television at least once a week. Exposure to print media is much less common; 9 percent of women and 17 percent of men reported reading a newspaper or magazine at least once a week.

Overall media exposure is higher among men than women; 13 percent of men are exposed to all three media at least once a week, as compared with 5 percent of women. Thirty-one percent of women and 14 percent of men age 15-49 are not exposed to any media source.

There is a wide gap in exposure to mass media by place of residence. For example, the proportion of newspaper readers is notably higher among urban women and men (12 percent and 26 percent, respectively) than among their rural counterparts (4 percent and 8 percent, respectively). Women and men residing in the Greater Accra region are most likely to be exposed to all three media on a weekly basis (11 percent and 24 percent, respectively).

Media exposure is highly related to the educational level as well as economic status of respondents. While 17 percent of women and 28 percent of men with a secondary or higher education access all three specific media at least once a week, 1 percent or less of those with no education or with primary education do so. Likewise, 12 percent of women and 31 percent of men in the highest wealth quintile access all three media at least once a week compared with less than 1 percent of women and 2 percent of men in the lowest quintile. The reason for the lower level of exposure to media among poor respondents may be that they are less likely to own a radio or television and, therefore, less likely to be consistently exposed to these media sources.

Table 3.5.1 Exposure to mass media: Women

Percentage of women age 15-49 who are exposed to specific media on a weekly basis, by background characteristics, Ghana 2014

3.6 EMPLOYMENT

3.6.1 Employment Status

The 2014 GDHS asked respondents a number of questions regarding their employment status, including whether they were working during the seven days preceding the survey and, if not, whether they had worked in the 12 months before the survey. The results for women and men are presented in Tables 3.6.1 and 3.6.2, respectively.

At the time of the survey, 73 percent of women were currently employed, and 3 percent were not currently employed but had worked sometime during the past 12 months (Figure 3.1).

Figure 3.1 Women's employment status in the past 12 months

12 months
3%

Currently employed
73%
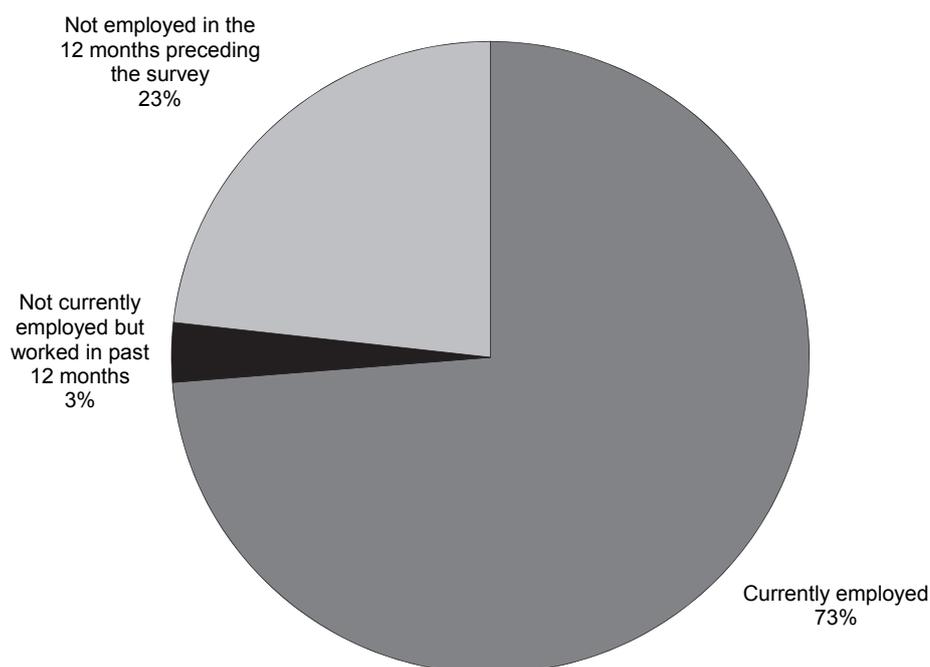

GDHS 2014

Table 3.6.1 shows that the proportion of women currently employed increases from 33 percent in the 15-19 age group to more than 90 percent for those age 40-44 and 45-49 (91 percent and 93 percent, respectively). Never-married women are less likely to be currently employed (50 percent) compared with currently or previously married women (85 percent and 88 percent, respectively). Current employment increases with the number of living children from 51 percent of women with no children to 89 percent among those with five or more children.

There are no notable variations in women's current employment by place of residence. Across regions, women in Ashanti are most likely to be currently employed (77 percent), while women in Eastern and Upper East regions are least likely to be currently employed (66 percent each).

Current employment among women decreases steadily with their level of education from 86 percent of women with no education to 66 percent of those with a secondary or higher education. There are no pronounced differences in women's current employment by wealth status.

Table 3.6.1 Employment status: Women

Percent distribution of women age 15-49 by employment status, according to background characteristics, Ghana 2014

| Background characteristic | Employed in the 12 months preceding the survey | | Not employed in the 12 months preceding the survey | Total | Number of women |

[1] "Currently employed" is defined as having done work in the past seven days. Includes persons who did not work in the past seven days but who are regularly employed and were absent from work for leave, illness, vacation, or any other such reason.

Table 3.6.2 shows that the proportion of men age 15-49 who are currently employed (82 percent) is higher than the proportion of women (73 percent). The percentage of currently employed men is lowest in the 15-19 age group (45 percent). Similar to women, never-married men (64 percent) and those with no living children (66 percent) are much less likely to be currently employed than ever-married men (96-99 percent) and men with living children (98-100 percent).

Men living in rural areas (86 percent) are more likely to be currently employed than men in urban areas (79 percent). Current employment among men ranges from 76 percent among residents of Upper West to 88 percent among men living in Brong Ahafo and Northern (88 percent each). Men with no education (99 percent) and those in the lowest wealth quintile (86 percent) are more likely to be currently employed when compared with the other subgroups.

Twenty-three percent of women and 15 percent of men were not employed during the 12 months preceding the survey.

[1] *Currently employed* is defined as having done work in the past seven days. Includes persons who did not work in the past seven days but who are regularly employed and were absent from work for leave, illness, vacation, or any other such reason.

3.6.2 Occupation

Respondents who were currently employed or who had worked in the 12 months preceding the survey were asked to state their occupation. The results presented in Tables 3.7.1 and 3.7.2 show the percent distribution of currently employed women and men by occupation, and background characteristics.

The type of occupation varies greatly by gender. The leading occupation among women is sales and services, which employs more than half of women (51 percent). Other occupations in which women are engaged include agriculture (24 percent), skilled manual labour (14 percent), professional, technical, or managerial work (7 percent), and unskilled manual labour and clerical positions (2 percent each).

Among men, on the other hand, agriculture is the leading occupation, with 35 percent of men engaged in this occupation. Twenty percent of men report doing skilled manual labour, 15 percent are engaged in unskilled manual labour, 14 percent do professional, technical, or managerial work or work in sales and services, and only 2 percent do clerical work.

The percentage of women and men age 15-49 who work in agriculture has decreased since the 2008 GDHS survey, dropping from 30 percent to 24 percent for women and from 41 percent to 35 percent for men.

The relationship between occupation and age varies. One notable finding is that the proportion of young women and men engaged in agriculture is relatively high among youth age 15-19 (28 percent for women and 53 percent for men); then it decreases somewhat, before it increases again for the older respondents age 40-49.

Table 3.7.1 Occupation: Women

Note: Totals may not add up to 100 percent because women with missing information are not shown separately.

Place of residence has a significant effect on type of occupation. As expected, a high proportion of respondents in rural areas, 46 percent of employed women and 61 percent of employed men—are engaged in agricultural work. Urban women (64 percent) are more likely to be engaged in sales and services, while urban men are more likely to be engaged in skilled manual labour (28 percent). Rural regions such as Northern have a high proportion of women and men who work in agriculture (64 percent and 75 percent, respectively). Urban regions, such as Greater Accra, by contrast, have a high proportion of women and men who work in sales and service (66 percent of women and 24 percent of men), and who do professional, technical or managerial work (12 percent of women and 22 percent of men). About one-fifth of women in Volta and Upper West regions (19 percent each) and more than one-quarter of men living in Greater Accra, Volta and Ashanti regions (26-27 percent) are engaged in skilled manual labor.

The percentage of respondents who work in agriculture decreases notably with increasing level of education and wealth. For example, 55 percent of women with no education work in agriculture compared with just 3 percent of those with a secondary or higher education. Furthermore, less than 1 percent of the wealthiest women work in agriculture compared with 69 percent of women in the lowest wealth quintile.

As expected, the opposite patterns are observed for professional, technical, or managerial work. The percentage of respondents who work in these fields is highest among those with a secondary or higher education and among the wealthiest respondents. The same pattern is also observed among men who work in sales in services.

3.6.3 Earnings, Employers, and Continuity of Employment

Table 3.8 shows the percent distribution of women age 15-49 employed in the 12 months preceding the survey by the type of earnings and employer, and continuity of employment, according to type of employment (agricultural or nonagricultural occupations).

Overall, 26 percent of employed women in the agricultural sector are not paid at all while 31 percent are paid in cash and in-kind. Women are more likely to be paid in cash if they are employed in the nonagricultural sector; 71 percent of women employed in the nonagricultural sector receive cash earnings, compared with 32 percent of women in the agriculture sector. Fourteen percent of women who work in the nonagricultural sector are not paid, and 13 percent are paid in cash and in-kind.

The large majority of women employed in the agricultural and nonagricultural sector are self-employed (70 percent and 66 percent, respectively). Twenty-seven percent of women working in agriculture are employed by family members (27 percent), as compared with only 9 percent of women working in the nonagricultural sector. The opposite pattern is observed for employment by nonfamily members; more than one in four women in the nonagricultural sector is employed by a nonfamily member (26 percent), compared with 4 percent of women who work in the agricultural sector.

Sixty-two percent of women who work in agriculture are employed throughout the year, compared with 88 percent of those who do nonagricultural work. Women are more likely to do seasonal work if they work in the agricultural sector than if they work in the nonagricultural sector (35 percent versus 8 percent).

Table 3.8 Type of employment: Women

Percent distribution of women age 15-49 employed in the 12 months preceding the survey by type of earnings, type of employer, and continuity of employment, according to type of employment (agricultural or nonagricultural), Ghana 2014

MARRIAGE AND SEXUAL ACTIVITY

4

Key Findings:

- Median age at first marriage increased somewhat between the 2008 and 2014 GDHS surveys, from 19.8 to 20.7 years among women age 25-49 and from 25.9 years to 26.4 years among men age 30-59.
- The proportion of women married by age 15 ranges from 2 percent among women age 15-19 to 11 percent among women age 45-49.
- Ghanaian men marry later than women.
- The proportion of currently married women and men in polygynous unions is on the decline. Over the last six years, it has decreased from 18 percent to 16 percent among women and from 9 percent to 7 percent among men age 15-49.
- The median age at first sexual intercourse among respondents age 25-49 is lower among women (18.4 years) than among men (19.8 years).
- Overall, 44 percent of never-married men have never had sexual intercourse, as compared with 38 percent of never-married women.
- Eleven percent women and 5 percent men age 25-49 had their first sex by age 15, and 44 percent of women and 27 percent of men had their first intercourse by age 18.
- Forty-three percent of women and 46 percent of men age 15-49 were sexually active during the four weeks preceding the survey.

This chapter discusses the principal factors other than contraception that affect women's chances of becoming pregnant. These factors include marriage and sexual activity. Marriage signals the onset of exposure to the risk of pregnancy for most women, and thus it is an important fertility indicator. In the context of the 2014 GDHS, marriage also includes living with partners in consensual but informal unions. In addition, this chapter includes information on more direct measures of the beginning of exposure to pregnancy and level of exposure, for example age at first sexual intercourse and frequency of recent sexual intercourse.

4.1 CURRENT MARITAL STATUS

Table 4.1 shows current marital status by age and sex. Fifty-seven percent of women and 48 percent of men age 15-49 are currently in a union; 42 percent and 38 percent, respectively, are married and 14 percent and 10 percent, respectively, are living together with a partner. A higher proportion of men (48 percent) than women (33 percent) have never been married. In combination, the percentage who are divorced, separated, or widowed is almost three times as high among women as among men (11 percent and 4 percent, respectively).

The proportion of women and men who have never been married decreases sharply with age, from more than 9 in 10 respondents age 15-19 to 1 percent of women and 4-5 percent of men in the 40-49 age group.

By contrast, the proportion of currently married women increases rapidly from 2 percent among women age 15-19 to 19 percent among those age 20-24 and peaks at 65 percent among women age 35-44. Among men, the percentage currently married also increases sharply with age, from less than 1 percent in the youngest age group to 5 percent among those age 20-24 and a high of 79-80 percent among men age 40-49.

The proportion of respondents who are divorced, separated, or widowed tends to increase with age among both women and men.

4.2 POLYGYNY

Marital unions are predominantly of two types, those that are monogamous and those that are polygynous. The distinction has social significance and probable fertility implications, although the association between union type and fertility is complex and not well understood. Polygyny, the practice of having more than one wife, has connotations for the frequency of sexual intercourse and thus may have an effect on fertility. The extent of polygyny in Ghana was measured by asking all currently married female respondents whether their husband or partner had other wives (co-wives) and, if so, how many. Currently married men were also asked whether they had one or more wives or partners with whom they were living.

Tables 4.2.1 and 4.2.2 show the percent distribution of currently married women with co-wives and the percentage of currently married men with two or more wives. The data show that, overall, the majority of Ghanaian women (84 percent) and men (93 percent) age 15-49 are in monogamous unions. Thirteen percent of women have one co-wife, and 2 percent have two or more co-wives.

The percentage of respondents in polygynous unions increases with age among both women and men. For example, 9 percent of women age 15-19 report that they have co-wives, as compared with 23 percent in the 45-49 age group. Polygyny is more prevalent in the rural areas, with 20 percent of women and 10 percent of men age 15-49 being in polygynous unions. Across the regions, polygyny among women is highest in Northern (42 percent) and lowest in Greater Accra (8 percent). Among men, it is highest in the Northern region (27 percent) and lowest in the Western, Central, and Ashanti regions (2 percent each).

The data further show that education and wealth are negatively associated with polygyny among both women and men. Thirty-one percent of women with no education are in a polygynous union compared with 5 percent of those with a secondary or higher education. Similarly, the percentage of men in a polygynous union decreases from 22 percent among those with no education to 3 percent among those with a secondary or higher education. Polygyny is highest among the poorest respondents; 36 percent of women and 23 percent of men in the lowest quintile are in a polygynous union.

Polygyny has decreased somewhat since the 2008 GDHS survey, from 18 percent to 16 percent among women and from 9 percent to 7 percent among men.

4.3 AGE AT FIRST MARRIAGE

Whether or not the start of marriage coincides with the initiation of sexual intercourse, and thus the beginning of exposure to the risk of pregnancy, it is an important social and demographic indicator and, in most societies, represents the point in a person's life when childbearing first becomes acceptable. Duration of exposure to the risk of pregnancy depends primarily on the age at which women first marry. Women who marry early, on average, are more likely to have their first child at a young age and give birth to more children overall, contributing to higher fertility.

Table 4.3 shows the percentage of women and men age 15-49 who have married by specific ages, according to current age. Age at first marriage is defined as the age at which the respondent began living with her or his first spouse/partner. Marriage occurs relatively early among women in Ghana; among women age 25-49, 45 percent were married by age 20 and 58 percent by age 22. The median age at first marriage among women age 25-49 is 20.7 years. The proportion of women married by age 15 declines from 11 percent in the 45-49 age group to 2 percent in the 15-19 age group, indicating a rising age at first marriage.

Men in Ghana generally marry later than women. Overall, 10 percent of men age 25-49 were married by age 20, compared with 45 percent of women the same age. Only 2 percent of men age 20-24

were married by age 18, as compared with 21 percent of women in the same age group. By age 25, 42 percent of men age 45-49 are married, compared with 83 percent of women.

na = Not applicable due to censoring
a = Omitted because less than 50 percent of the respondents began living with their spouse or partner for the first time before reaching the beginning of the age group

4.4 MEDIAN AGE AT FIRST MARRIAGE

Table 4.4 presents the median age at first marriage for women age 25-49 and men age 30-59 according to background characteristics. The data show that median age at first marriage is 20.7 years among women and 26.4 years among men.

Urban women marry 3.5 years later than rural women (22.7 years versus 19.2 years). By region, women in Northern marry the earliest, at a median age of 18.7 years, and women in Greater Accra marry the latest, at a median age of 23.7 years, a five-year difference.

The data further show that women with no education or with a primary education (18.8 years each) and those in the lowest wealth quintile (18.7 years) marry at a lower median age than women in the other subgroups.

Similar patterns are observed among men. Among men age 30-59, those living in urban areas marry more than three years later than their rural counterparts (28.2 years and 24.9 years, respectively). Men in Greater Accra have the highest median age at first marriage (28.7 years) and men in Upper East have the lowest median (24.4 years). Men with no education marry at a median age of 24.5 years, more than five years earlier than men with a secondary or higher education, who have a median age at first marriage of 29.6 years. Similar to women, median marriage at first marriage among men increases with wealth and is lowest among the poorest men (24.6 years).

Median age at first marriage increased somewhat between the 2008 and 2014 GDHS surveys, from 19.8 to 20.7 years among women age 25-49 and from 25.9 years to 26.4 years among men age 30-59.

4.5 AGE AT FIRST SEXUAL INTERCOURSE

Age at first marriage is often used as a proxy for the onset of women's exposure to the risk of pregnancy. However, because some women are sexually active before marriage, the age at which women initiate sexual intercourse more precisely marks the beginning of their exposure to pregnancy. Information on age at first sexual intercourse allows an assessment of trends across age cohorts.

Table 4.5 shows the percentage of women and men who had first sexual intercourse by specific ages and the median age at first intercourse, irrespective of marital status. The data show that among women age 25-49, 11 percent had their first sexual intercourse by age 15, 44 percent by age 18, and 68 percent by age 20. The median age at first intercourse among women age 25-49 is 18.4 years, more than two years lower than the median age at first marriage (20.7 years), suggesting that Ghanaian women in general initiate sexual intercourse before their first marriage.

The median age at first sexual intercourse among men age 25-49 is 19.8 years, higher than among women in the same age group (18.4 years). Among men age 25-49, 5 percent had their first sexual intercourse by age 15, 27 percent by age 18, and 52 percent by age 20. Among respondents age 15-24, a substantially higher proportion of men (53 percent) than women (35 percent) have never had intercourse. However, within the 25-49 age group, just 1 percent of women and 2 percent of men have never had sexual intercourse.

Table 4.4 Median age at first marriage by background characteristics

a = Omitted because less than 50 percent of the respondents had sexual intercourse for the first time before reaching the beginning of the age group

4.6   MEDIAN AGE AT FIRST SEXUAL INTERCOURSE

Table 4.6 shows the median age at first sexual intercourse among women age 20-49 and 25-49 and among men age 20-59 and 25-59 by background characteristics.

Urban women initiate sexual intercourse at a higher median age than their rural counterparts. The median age at first sexual intercourse among urban women age 25-49 is 18.8 years, one year later than their rural counterparts (17.8 years). By region, the median age at first sexual intercourse among women is highest in Greater Accra (19.0 years) and lowest in Northern (17.5 years).

Women age 25-49 with no education and those with a primary education have the lowest median age at first sexual intercourse (17.5 years and 17.2 years, respectively), and those with a secondary or higher education have the highest median age (20.6 years). Similarly, when looking at wealth, women in the lowest three quintiles have a lower median age at first sexual intercourse (17.5-17.7 years) than women in the highest quintile (19.9 years).

Table 4.6 further shows that the median age at first sexual intercourse is 19.8 years among men age 20-59 and 20.0 years among those age 25-59. Median age at first sexual intercourse is slightly higher among urban than rural men age 25-59 (20.1 years and 19.8 years, respectively). It is highest in Greater Accra (20.3 years) and lowest in Volta (18.8 years). Men's level of education and wealth do not show a clear relationship with their median age at first intercourse.

4.7 RECENT SEXUAL ACTIVITY

In the absence of contraception, the possibility of pregnancy is related to the frequency of sexual intercourse. Thus, information on intercourse is important for refining measurement of exposure to pregnancy. All women and men were asked how long ago their last sexual contact occurred. Tables 4.7.1 and 4.7.2 show the percent distribution of women and men age 15-49, respectively, by the timing of their last sexual intercourse, according to background characteristics.

Table 4.7.1 shows that 43 percent of women age 15-49 were sexually active during the four weeks preceding the survey. Twenty-eight percent had been sexually active in the 12 months preceding the survey but not in the past month, and 16 percent had not been sexually active for one or more years. One in eight women (13 percent) had never had sexual intercourse.

Table 4.6 Median age at first sexual intercourse by background characteristics

Median age at first sexual intercourse among women age 20-49 and age 25-49, and median age at first sexual intercourse among men age 20-59 and age 25-59, according to background characteristics, Ghana 2014

Background characteristic	Women age		Men age

Total	18.4	18.4	19.8	20.0

a = Omitted because less than 50 percent of the respondents had intercourse for the first time before reaching the beginning of the age group

The proportion of women who were sexually active in the four weeks preceding the survey is lowest among those age 15-19 (14 percent) and highest among those age 40-44 (56 percent). The data further show that never-married and previously married women are much less likely to have had sexual intercourse in the last four weeks (18 percent and 19 percent, respectively) than women currently in a union (63 percent).

The proportion of women who were sexually active within the four weeks prior to the survey fluctuates by marital duration: it is lowest among those who have been married for 25 or more years (57 percent) compared with those married for shorter periods of time (62-64 percent).

The results further show that a higher proportion of women in rural areas (46 percent) were sexually active within the last four weeks than women in urban areas (41 percent). There are marginal variations in recent sexual activity among women across regions; recent sexual activity is highest in Brong Ahafo (48 percent) and lowest in the Upper West region (35 percent).

Women with no education (50 percent) and those in the lowest, second and highest wealth quintiles (44-45 percent) are more likely to have had recent sexual activity than other women.

[1] Excludes women who had sexual intercourse within the last 4 weeks
[2] Excludes women who are not currently married

Table 4.7.2 shows that less than half of men age 15-49 (46 percent) were sexually active in the four weeks preceding the survey, about one in four (24 percent) were sexually active in the past year but not in the past four weeks, and 9 percent had not been sexually active for one or more years. About one in five men (21 percent) had never had sexual intercourse.

The proportion of men who were sexually active in the four weeks preceding the survey is lowest in the 15-19 age group (7 percent) and highest among men age 35-49 (70-73 percent). Similar to women, men who have never been married (18 percent) and those who are divorced, separated, or widowed (46 percent) are substantially less likely to have had recent sexual intercourse than men who are married or cohabiting with a partner (74 percent).

There are no major variations in recent sexual activity among men according to marital duration or urban-rural residence. By region, men in Eastern are most likely to have been sexually active in the past four weeks (51 percent), while men in Northern are least likely to have been recently active (34 percent).

Table 4.7.2 Recent sexual activity: Men

[1] Excludes men who had sexual intercourse within the last 4 weeks
[2] Excludes men who are not currently married

A comparison of data between the 2008 and 2014 GDHS surveys shows a slight increase in recent sexual activity among women and men age 15-49, from 40 percent each in 2008 to 43 percent and 46 percent, respectively, in 2014.

FERTILITY

5

Key Findings:

- The total fertility rate for the three years preceding the survey is 4.2 children per woman, with rural women having 1.7 children more than urban women.
- Fertility has declined from 6.4 children per woman in the 1988 GDHS to 4.2 children per woman in the 2014 GDHS—a drop of two births per woman over the past twenty-six years. There has been a slight increase in the TFR over the past six years, from 4.0 to 4.2 children per woman.
- More than 1 in 10 non-first births (13 percent) occur after too short an interval following a preceding birth (less than 24 months).
- The median age at first birth among women age 25-49 is 21.4 years.
- About one-fifth of Ghanaian women age 25-49 (22 percent) have given birth before reaching age 18, while nearly two-fifths (39 percent) have given birth by age 20.
- Ghanaian women are amenorrhoeic for a median of 8.4 months, abstain for a median of 5.9 months, and are insusceptible to pregnancy for a median of 10.4 months.
- Ten percent of women age 30-49 are menopausal.
- Overall, 14 percent of women age 15-19 have begun childbearing, either having had a live birth (11 percent) of having become pregnant with their first child (3 percent).

Fertility is one of the three principal components of population dynamics that determine the size, structure, and composition of the population in any country. The government of Ghana initiated its first national population policy in 1969 to manage population resources in a consistent manner. This approach was consistent with the government's ultimate objective to accelerate the rate of economic development and improve the quality of life of the people. After 25 years of its promulgation, population growth still remained unacceptably high. As a result, the population policy was revised in 1994 to include a systematic integration of population in development planning with renewed emphasis on fertility reduction to accelerate economic modernisation, sustainable development, and poverty eradication (NPC 1994). Since then, Ghana has made substantial progress in reducing fertility. One of the major indicators of fertility provided by the DHS surveys in Ghana is the current fertility rate, which is critical to the development of population policies and programmes.

One of the main objectives of the 2014 GDHS was to examine fertility levels, trends, and differentials in Ghana. This chapter focuses on a number of fertility indicators including levels, patterns, and trends in both current and cumulative fertility; the length of birth intervals; and the age at which women begin childbearing. Birth intervals are important because short intervals are associated with high childhood mortality. The age at which childbearing begins can also have a major impact on the health and well-being of both the mother and the child.

The fertility indicators presented in this chapter are based on reports of reproductive histories provided by women age 15-49. As in the previous GDHS surveys, each woman was asked to provide information on the total number of sons and daughters to whom she had given birth and who were living with her, the number living elsewhere, and the number who had died, in order to obtain the total number of live births. In the birth history, women reported the details of each live birth separately, including such

information as name, and month and year of birth, in addition to sex and survival status. For children who had died, age at death was recorded.

5.1 CURRENT FERTILITY

Measures of current fertility include age-specific fertility rates (ASFRs), the total fertility rate (TFR), the general fertility rate (GFR), and the crude birth rate (CBR). These rates are presented for the three-year period preceding the survey, a period that covers a portion of calendar years 2012 through 2014. A three-year period (rather than a longer or a shorter period) was chosen to calculate rates as a balanced response to providing the most current information, reducing sampling error, and avoiding problems caused by the displacement of births.

Age-specific fertility rates aid in understanding the age pattern of fertility. Numerators of ASFRs are calculated by identifying live births that occurred in the period 1 to 36 months preceding the survey (determined from the date of interview and date of birth of the child); they are then classified by the age of the mother (in five-year groups) at the time of the child's birth. The denominators of these rates are the number of woman-years lived by the survey respondents in each of the five-year age groups during the specified period.

The TFR is a common measure of current fertility and is defined as the number of children a woman would have by the end of her childbearing years if she were to pass through those years bearing children at the current age-specific fertility rates. The GFR represents the number of live births per 1,000 women of reproductive age. The CBR is the number of live births per 1,000 population. The latter two measures are based on birth history data for the three-year period preceding the survey and on the age-sex distribution of the household population.

Table 5.1 shows the age-specific and aggregate fertility measures calculated from the 2014 GDHS. The total fertility rate for Ghana is 4.2 children per woman, a slight increase from 4.0 children per woman in the 2008 GDHS survey. Childbearing peaks during age group 25-29 and drops sharply after age 39. Rural women have about 1.7 children more than urban women (5.1 children per woman compared with 3.4 children per woman). The pattern of lower fertility in urban areas is evident in every age group, and it is most pronounced for women in the 20-24 age group (121 births per 1,000 women in urban areas compared with 210 births per 1,000 women in rural areas).

Table 5.1 Current fertility

Age-specific and total fertility rates, the general fertility rate, and the crude birth rate for the three years preceding the survey, by residence, Ghana 2014

Age group	Residence		
	Urban	Rural	Total
15-19	53	100	76
20-24	121	210	161
25-29	181	228	201
30-34	178	223	197
35-39	110	164	135
40-44	34	72	52
45-49	12	21	17
TFR (15-49)	3.4	5.1	4.2
GFR	120	171	143
CBR	28.2	33.1	30.6

Notes: Age-specific fertility rates are per 1,000 women. Rates for age group 45-49 may be slightly biased due to truncation. Rates are for the period 1-36 months prior to interview.
TFR: Total fertility rate expressed per woman
GFR: General fertility rate expressed per 1,000 women age 15-44
CBR: Crude birth rate expressed per 1,000 population

One of the main targets of the 1994 revised National Population Policy was to reduce the total fertility rate from 5.5 to 5.0 children per woman by the year 2000, to 4.0 by 2010, and to 3.0 by 2020 (NPC 1994). With a TFR of 4.0 in 2008, Ghana achieved its fertility target two years before the target year of 2010. However, with the slight increase in fertility reported in the 2014 GDHS, more needs to be done to reach the TFR target of 3.0 children per woman by the year 2020. The TFR in Ghana however, is still one of the lowest in sub-Saharan Africa (Figure 5.1).

Figure 5.1 Total fertility rates, selected Sub-Saharan African countries
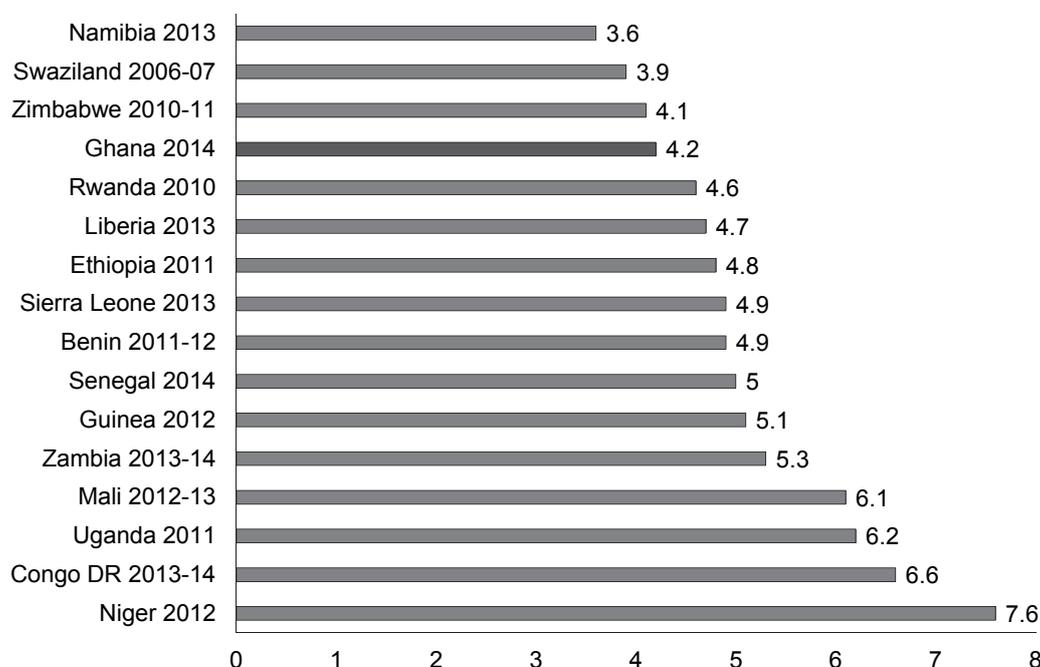

Note: Rates are per 1,000 women and refer to the three-year period preceding the survey.

5.2 FERTILITY DIFFERENTIALS

Table 5.2 shows differentials in fertility by residence, region, education, and wealth quintile. The TFR varies among regions, ranging from 2.8 children per woman in the Greater Accra region to 6.6 children per woman in the Northern region. The level of fertility is inversely related to women's educational attainment, decreasing rapidly from 6.2 children among women with no education to 2.6 children among women with a secondary or higher level of education. Fertility also decreases with wealth; women in the lowest wealth quintile have an average of 6.3 children compared with 2.8 children among women in the highest wealth quintile.

Table 5.2 also presents a crude assessment of trends among the various subgroups by comparing current fertility with a measure of completed fertility: the mean number of children ever born to women age 40-49. The mean number of children ever born to older women who are nearing the end of their reproductive period is an indicator of average completed fertility of women who began childbearing during the three decades preceding the survey. If fertility remained constant over time and the reported data on both children ever born and births during the three years preceding the survey are reasonably accurate, the TFR and the mean number of children ever born to women 40-49 are expected to be similar. When fertility levels are falling, the TFR will be substantially lower than the mean number of children ever born among women age 40-49.

Overall, a comparison of past (completed) and current (TFR) fertility indicators suggests a slight difference (4.8 versus 4.2) between the two. Current fertility is slightly higher than past fertility among women in the Northern region, among women with no education, and among those with middle/JSS/JHS education.

Table 5.2 Fertility by background characteristics

Total fertility rate for the three years preceding the survey, percentage of women age 15-49 currently pregnant, and mean number of children ever born to women age 40-49 years, by background characteristics, Ghana 2014

Background characteristic	Total fertility rate	Percentage of women age 15-49 currently pregnant	Mean number of children ever born to women age 40-49
Residence			
Urban	3.4	6.5	4.1
Rural	5.1	7.7	5.6
Region			
Western	3.6	6.9	4.8
Central	4.7	7.8	5.2
Greater Accra	2.8	6.9	3.4
Volta	4.3	6.1	4.8
Eastern	4.2	7.9	4.9
Ashanti	4.2	5.8	4.8
Brong Ahafo	4.8	7.6	5.1
Northern	6.6	8.9	6.4
Upper East	4.9	7.9	5.7
Upper West	5.2	6.8	6.4
Education			
No education	6.2	8.8	5.9
Primary	4.9	6.6	5.2
Middle/JSS/JHS	4.2	7.0	4.1
Secondary+	2.6	6.1	2.6
Wealth quintile			
Lowest	6.3	7.9	6.6
Second	5.5	7.6	5.8
Middle	3.9	7.0	4.8
Fourth	3.5	5.7	4.0
Highest	2.8	7.4	3.2
Total	4.2	7.1	4.8

Note: Total fertility rates are for the period 1-36 months prior to interview.

Table 5.2 also shows the percentage of women 15-49 who reported being pregnant at the time of the survey. This percentage may be underreported because women may be unaware of a pregnancy, especially at the early stages, and some women who are early in their pregnancy may not want to reveal that they are pregnant. Nationally, 7 percent of women were pregnant at the time of the survey, with minor variations by background characteristics. Rural women (8 percent) are slightly more likely to report being currently pregnant than urban women (7 percent). At the regional level, the proportion of pregnant women is highest in the Northern region (9 percent) and lowest in the Volta and Ashanti regions (6 percent each). The proportion of women currently pregnant is highest among women with no education (9 percent) and women in the lowest and second wealth quintiles (8 percent each).

5.3   FERTILITY TRENDS

In addition to the comparison of current and completed fertility, trends in fertility can be assessed in two other ways. First, fertility trends can be investigated using retrospective data on birth histories collected in the 2014 GDHS. Second, the TFR from the 2014 GDHS can be compared with estimates obtained in earlier surveys.

Table 5.3.1 shows trends in age-specific fertility rates for five-year periods preceding the survey, by mother's age at the time of birth. The table uses information from the retrospective birth histories obtained from the 2014 GDHS respondents to examine trends in age-specific fertility rates for successive five-year periods before the survey. To calculate these rates, births were classified according to the period of time in which the birth occurred and the mother's age at the time of the birth. Because women age 50 and above were not interviewed in the survey, the rates are successively truncated for periods more distant from the survey date. For example, rates cannot be calculated for women age 35-39 for the period 15 to 19 years before the survey because these women would have been over age 50 at the time of the survey and thus would not have been interviewed.

Fertility has fallen gradually among women in all age groups over the past two decades, with the exception of the 25-29 age group. The decrease in fertility is steepest among women age 15-19, a 20 percent decline between the 15-19 year period before the survey and 0-4 year period before the survey.

Table 5.3.2 and Figure 5.2 compare fertility trends from estimates obtained in the 1988, 1993, 1998, 2003, and 2008 GDHS with information gathered in the 2014 GDHS. Fertility has declined from 6.4 children per woman in the 1988 GDHS to 4.2 children per woman in the 2014 GDHS—a drop of two children per woman over the past 26 years. There has been a slight increase in the TFR over the past six years, from 4.0 to 4.2 children per woman.

Table 5.3.1 Trends in age-specific fertility rates

Age-specific fertility rates for five-year periods preceding the survey, by mother's age at the time of the birth, Ghana 2014

	Number of years preceding survey			
Mother's age at birth	0-4	5-9	10-14	15-19
15-19	73	84	88	91
20-24	159	167	184	193
25-29	200	203	230	216

Note: Age-specific fertility rates are per 1,000 women.

Figure 5.2 Trends in age-specific fertility rates
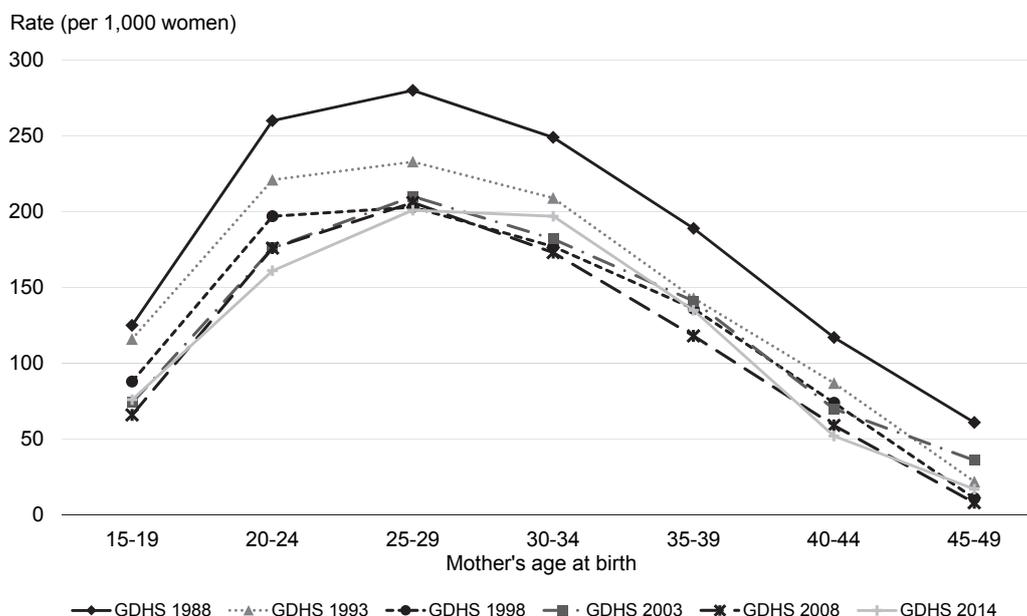

5.4   CHILDREN EVER BORN AND LIVING

Data on the number of children ever born reflect accumulated births over the past 30 years and therefore have limited relevance to current fertility levels, particularly when the country has experienced a decline in fertility. Moreover, the data are subject to recall error, which is typically greater for older than younger women. Nevertheless, information on children ever born (or parity) is useful in looking at a number of issues. Parity data show how average family size varies across age groups. The percentage of currently married women in their 40s who have never had children also provides an indicator of the level of primary infertility or the inability to bear children. Comparisons of differences in the mean number of children ever born and surviving reflect the cumulative effects of mortality levels during the period in which women have been bearing children.

Table 5.4 shows the percent distribution of all women and currently married women by number of children ever born, mean number of children ever born, and mean number of children living. Eighty-nine percent of women age 15-19 have never given birth. This proportion declines to 25 percent among women age 25-29 and to less than 10 percent among women age 30 or older, indicating that childbearing among Ghanaian women is nearly universal. On average, Ghanaian women nearing the end of their reproductive years have attained a parity of 5.0 children, about one child more than the total fertility rate of 4.2. The same pattern is observed among currently married women, except that the mean number of children ever born is higher among currently married women (3.4 children) than among all women (2.4 children). The difference between all women and currently married women in the mean number of children ever born is due to the substantial proportion of young and unmarried women in the former category who exhibit lower fertility.

Table 5.4 Children ever born and living

Percent distribution of all women and currently married women age 15-49 by number of children ever born, mean number of children ever born, and mean number of living children, according to age group, Ghana 2014

Total	6.5	14.7	18.1	17.5	14.5	11.2	7.8	4.6	2.3	1.8	1.0	100.0	5,321	3.42	3.12

As expected, the mean number of children ever born and the mean number of children surviving increase with women's age. A comparison of the mean number of children ever born with the mean number of living children reveals the experience of child loss among Ghanaian women. By the end of their reproductive years (age 45-49), women in Ghana have given birth to an average of 2.4 children, with 2.1 surviving.

Voluntary childlessness is uncommon in Ghana. Currently married women with no children are likely to be those who are sterile or unable to bear children. The level of childlessness among married women at the end of their reproductive period can be used as an indicator of the level of primary sterility. In Ghana, primary sterility among currently married women age 45-49 is 2 percent.

5.5 BIRTH INTERVALS

Birth interval is the length of time between two successive live births. Information on birth intervals provides an insight into birth spacing patterns, which affect fertility as well as maternal, infant, and childhood mortality. Studies have shown that short birth intervals are associated with increased risk of death for both mother and baby, particularly when the birth interval is less than 24 months.

Table 5.5 shows the percent distribution of non-first births in the five years preceding the survey by number of months since the preceding birth, according to background characteristics. The median birth interval in Ghana is 39 months, a slight decrease from the median of 40 months reported in the 2008 GDHS. More than 1 in 10 non-first births (13 percent) occur after too short an interval (less than 24 months) following a preceding birth.

The median number of months since a preceding birth increases significantly with age, from 35.2 months for births to mothers age 20-29 to 47.6 months for births to mothers age 40-49. There is no marked difference in the length of the median birth interval by sex of the preceding birth.

Death of a preceding child usually leads to a shorter birth interval than when the preceding child survived. The median birth interval is almost 11 months shorter among births in which the previous sibling is dead than among births in which the previous sibling is alive (28.9 months versus 40.2 months). This difference in birth intervals may be due to the desire of parents to replace a dead child, as well as the loss of the fertility-delaying effects of breastfeeding.

The median birth interval decreases with increasing birth order, from 40.6 months for births of the second or third order to 34.2 months for births of the seventh or higher order. By residence, the median birth interval is longer in urban than in rural areas (41.6 months versus 38.2 months). The longest median birth interval is in Upper East (44.8 months), and the shortest is in Central (37.1 months). There are no clear patterns in the relationship between median birth interval and mother's education. The median birth interval generally increases by wealth, although the increase is not linear.

Table 5.5 Birth intervals

Percent distribution of non-first births in the five years preceding the survey by number of months since preceding birth, and median number of months since preceding birth, according to background characteristics, Ghana 2014

Background characteristic	Months since preceding birth						Total	Number of non-first births	Median number of months since preceding birth

Total	3.6	9.5	30.3	20.9	13.1	22.7	100.0	4,308	39.4

Note: First-order births are excluded. The interval for multiple births is the number of months since the preceding pregnancy that ended in a live birth. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

5.6 Postpartum Amenorrhoea, Abstinence, and Insusceptibility

Postpartum amenorrhoea is the interval between the birth of a child and the resumption of menstruation, a period during which the risk of pregnancy is much reduced. Postpartum protection from conception depends upon the intensity and duration of breastfeeding. Postpartum abstinence refers to the period of voluntary sexual inactivity after childbirth. A woman is considered insusceptible if she is not exposed to the risk of pregnancy, either because she is amenorrhoeic or because she is abstaining from sexual intercourse following a birth. In the 2014 GDHS, information was obtained about the duration of amenorrhoea and sexual abstinence following childbirth for births in the three years preceding the survey.

Table 5.6 shows that Ghanaian women are amenorrhoeic for a median of 8.4 months, abstain for a median of 5.9 months, and are insusceptible to pregnancy for a median of 10.4 months. In general, the proportion of women who are amenorrhoeic or abstaining decreases with increasing months after delivery.

The proportion of women who are amenorrhoeic drops from 96 percent in the first two months after birth to 21 percent at 12-15 months and to 2 percent or less at 30 months or later. The majority of Ghanaian women (98 percent) are still abstaining in the first two months following a birth.

Table 5.6 Postpartum amenorrhoea, abstinence, and insusceptibility

Percentage of births in the three years preceding the survey for which mothers are postpartum amenorrhoeic, abstaining, and insusceptible, by number of months since birth, and median and mean durations, Ghana 2014

Months since birth	Percentage of births for which the mother is:			Number of births
	Amenorrhoeic	Abstaining	Insusceptible[1]	
< 2	96.2	97.8	98.4	136

Mean	10.2	9.4	13.2	na

Note: Estimates are based on status at the time of the survey.
na = Not applicable
[1] Includes births for which mothers are either still amenorrhoeic or still abstaining (or both) following birth

Table 5.7 shows the median duration of postpartum amenorrhoea, abstinence, and insusceptibility by background characteristics. The median duration of postpartum insusceptibility is 10.0 months among women age 15-29, compared with 11.3 months among women age 30-49. By residence, the median duration of postpartum insusceptibility is higher among rural (11.7 months) than urban women (9.5 months). Women in Upper West have the longest median duration of postpartum insusceptibility (15.9 months), while women in Western have the shortest median duration (7.9 months).

Median duration of postpartum insusceptibility decreases sharply with education and wealth. For example, it decreases from 13.9 months among women with no education to 7.2 months among those with a secondary or higher education. Similarly, women in the lowest wealth quintile are insusceptible almost two times longer than women in the highest wealth quintile (13.0 months compared with 6.6 months).

Table 5.7 Median duration of amenorrhoea, postpartum abstinence, and postpartum insusceptibility

Median number of months of postpartum amenorrhoea, postpartum abstinence, and postpartum insusceptibility following births in the three years preceding the survey, by background characteristics, Ghana 2014

[1] Includes births for which mothers are either still amenorrhoeic or still abstaining (or both) following birth

5.7 MENOPAUSE

The risk of becoming pregnant declines with age. The term infecundity refers to a process rather than a well-defined event, and although the onset of infecundity is difficult to determine for an individual woman, there are ways of estimating it for a group of women. Table 5.8 presents data on menopause, an indicator of decreasing exposure to the risk of pregnancy (infecundity) for women age 30 and older.

In the 2014 GDHS, women were considered menopausal if they were neither pregnant nor postpartum amenorrhoeic and had not had a menstrual period for at least six months preceding the survey. The proportion of women who were menopausal at the time of the survey increases with age, from 2 percent among women age 30-34 to 39 percent among women age 48-49. Overall, 10 percent of women age 30-49 were menopausal.

Table 5.8 Menopause

Percentage of women age 30-49 who are menopausal, by age, Ghana 2014

Age	Percentage menopausal[1]	Number of women
30-34	2.2	1,372
35-39	3.5	1,295
40-41	7.0	450
42-43	8.7	413
44-45	19.6	398
46-47	32.1	317
48-49	39.2	309
Total	9.7	4,554

[1] Percentage of all women who are not pregnant and not postpartum amenorrhoeic whose last menstrual period occurred six or more months preceding the survey

5.8 AGE AT FIRST BIRTH

The onset of childbearing at an early age has a major effect on the health of both mother and child. It also lengthens the reproductive period, thereby increasing the level of fertility. Table 5.9 shows the median age at first birth and the percentage of women who gave birth by exact ages, according to current age. The median age at first birth among women age 25-49 is 21.4 years.

About one-fifth of Ghanaian women age 25-49 (22 percent) had given birth before reaching age 18, while nearly two-fifths (39 percent) have given birth by age 20. The median age at first birth has increased gradually from 20.3 years for older women 45-49 to 22.6 years for women age 25-29 – the youngest cohort for whom a median age can be computed – indicating an increase in age at first birth over the last 20 years.

Table 5.9 Age at first birth

Percentage of women age 15-49 who gave birth by exact ages, percentage who have never given birth, and median age at first birth, according to current age, Ghana 2014

| Current age | Percentage who gave birth by exact age | | | | | Percentage who have never given birth | Number of women | Median age at first birth |
	15	18	20	22	25			
15-19	0.5	na	na	na	na	88.7	1,625	a

na = Not applicable due to censoring
a = Omitted because less than 50 percent of women had a birth before reaching the beginning of the age group

Table 5.10 shows the median age at first birth for different age cohorts across please of residence, region, education, and wealth status. Median age at first birth is higher in urban areas than in rural areas. Among women age 30-49, median age at first birth is 22.2 months in urban areas compared with 20.1 months in rural areas. Among the same group of women, median age at first birth is highest in the Greater Accra region (23.4 years) and lowest in the Central, Northern, and Upper East regions (20.0 years each). There is a direct relationship between the median age at first birth and education and wealth. Median age at first birth is 19.9 years and 19.6 years among women age 30-49 with no education and with primary education, respectively, as compared with 27.0 years among women with a secondary or higher education. Women age 30-49 in the lowest two wealth quintiles have their first birth almost five years earlier than women in the highest quintile (19.9 years versus 24.7 years).

5.9   TEENAGE PREGNANCY AND MOTHERHOOD

Teenage pregnancy and motherhood is a major social and health issue in Ghana. Early teenage pregnancy can cause severe health problems for both the mother and child. Moreover, an early start to childbearing greatly reduces women's educational and employment opportunities and is associated with higher levels of fertility.

Table 5.11 shows that 14 percent of women age 15-19 have begun childbearing; either they have had a live birth (11 percent) or are pregnant with their first child (3 percent), a slight increase from 13 percent in 2008. The percentage of women who have begun childbearing increases rapidly with age, from 2 percent among women age 15 to 36 percent among women age 19.

Table 5.10 Median age at first birth

Median age at first birth among women age 25-49 and age 30-49, according to background characteristics, Ghana 2014

Background characteristic	Women age 25-49	Women age 30-49

Total	21.4	21.1

a = Omitted because less than 50 percent of the women had a birth before reaching the beginning of the age group

Teenage childbearing is higher in rural areas (17 percent) than in urban areas (12 percent). By region, the percentage of teenage women who have begun childbearing ranges from 8 percent in the Greater Accra region to 22 percent in the Volta region. Not surprisingly, early childbearing is inversely related to women's educational level. Teenagers with no education are almost four times as likely to have begun childbearing as those with a secondary or higher education (23 percent and 6 percent, respectively). The percentage of teenagers who have begun childbearing is highest in the second wealth quintile (21 percent) and lowest in the wealthiest households (6 percent).

FERTILITY PREFERENCES

6

> **Key Findings:**
>
> - More than 3 in 10 women (35 percent) and men (31 percent) do not want any more children; another 2 percent of women but less than 1 percent of men have been sterilised.
> - Women and men in Ghana prefer a big family: 4.3 children for all women and 4.5 children for all men, among those age 15-49. The preference among married women and men is for 4.7 and 5.1 children.
> - Overall, Ghanaian women have about 0.6 children more than their ideal number, implying that the total fertility rate of 4.2 children per woman is 17 percent higher than it would be if unwanted births were avoided.

H igh fertility rates and large family size have persisted in most sub-Saharan African countries despite the implementation of policies and programmes aimed at reducing births (Garenne 2008). The primary objective of Ghana's 1994 Population Policy is to promote a small family size through information and education campaigns and to target a two-year minimum interval between all births by 2020. The government has since then actively promoted the voluntary acceptance of family planning methods. All couples are being encouraged to decide freely and responsibly on the timing, number, and spacing of their children for a family size that can be managed (NPC 1994).

This chapter describes fertility preferences, the ideal and actual number of children as well as the wanted and actual fertility rates. Information on fertility preferences is used to assess future fertility patterns and potential demand for contraception. Such data are also useful in constructing measures of unwanted or mistimed births.

6.1 Desire for More Children

Information about the desire for more children is important for understanding future reproductive behaviour. The provision of adequate and accessible family planning services depends on the availability of such information. In the 2014 GDHS, currently married women (whether pregnant or not) and men were asked about their intentions to have another child and, if they had such intentions, how soon they wanted the child. The same question was phrased differently in the case of pregnant women or men whose wife or wives (or partners) were pregnant at the time of the interview. This was done to ensure an accurate answer about the desire of subsequent children after completion of the current pregnancy. Sterilised women and men were considered to want no more children, and therefore were not asked questions about their desire for more children.

Table 6.1 shows that 19 percent of women and 22 percent of men age 15-49 want to have another child soon (within two years), while 31 percent of women and 38 percent of men want another child two or more years later. More than 3 in 10 women (35 percent) and men (31 percent) do not want any more children, and 2 percent of women and less than 1 percent of men have been sterilised. The proportion of both women and men who want to have a child soon is inversely associated with the number of living children. Seven in 10 currently married women with no living children (71 percent) want to have a child soon, as compared with 4 percent of women with six or more children. Among currently married men with no living children, more than 6 in 10 (63 percent) want to have a child soon, compared with 9 percent of men with six or more children.

The desire to limit childbearing (including by undergoing sterilisation) increases with the number of living children, from 7 percent among childless women and 2 percent among women with one child to 78 percent among those with six or more children. Less than 1 percent of women with one or two children have been sterilised compared with 5 percent of women with six or more children.

A comparison of the findings from the five GDHS surveys shows that the desire to space births among currently married Ghanaian women has declined over time, while the desire to limit births has increased, showing some improvement as a result of efforts to limit the number of births per woman in Ghana. However, these changes have been minimal in the past six years.

Similar to women, the desire to have no more children increases from 3 percent among currently married men age 15-49 with one child to 60 percent among those with six or more children. Men are slightly more likely to want to limit childbearing at lower parities than women, while the opposite is true for the higher parities. For example, 3 percent of men with one child desire to stop childbearing or have been sterilised, compared with 2 percent of women with one child. On the other hand, 73 percent of women with six or more children desire to stop childbearing or have been sterilised, compared with 60 percent of men in the same category.

Table 6.1 Fertility preferences by number of living children

Percent distribution of currently married women and currently married men age 15-49 by desire for children, according to number of living children, Ghana 2014

[2] Wants next birth within two years
[3] Wants to delay next birth for two or more years
[4] Includes both female and male sterilisation
[5] Number of living children includes one additional child if respondent's wife is pregnant (or if any wife is pregnant for men with more than one current wife)

6.2 DESIRE TO LIMIT CHILDBEARING BY BACKGROUND CHARACTERISTICS

Tables 6.2.1 and 6.2.2 provide information on differences in potential demand for fertility control by background characteristics. Even though nationally there are no notable differences by residence, at all parity levels, urban women are more likely to want to limit childbearing than rural women. Generally, women in southern Ghana are more likely than women in the four northern regions (Brong Ahafo, Northern, Upper East, and Upper West) to want no more children. This proportion ranges from 17 percent of women in the Northern region to 48 percent each, of women in the Eastern and Volta regions. Women

with a secondary or higher education (28 percent) are the least likely to want no more children, as compared with 36 to 42 percent of women with no education or with primary education. There are no clear patterns by wealth; however, women in the second wealth quintile are notably more likely to want to limit childbearing (46 percent) when compared with women in the other wealth quintiles (32-39 percent).

Among men, the desire to limit childbearing fluctuates by urban-rural residence at each parity level. The total percentage wanting no more children is similar among men in urban and in rural areas (31 percent and 32 percent, respectively). By region, the percentage of men who want no more children ranges from 9 percent in Northern to 49 percent in Eastern. Men with no education (19 percent) and those in the lowest wealth quintile (20 percent) are the least likely to want no more children compared with men in the other education and wealth categories (Table 6.2.2).

Note: Men who have been sterilised or who state in response to the question about desire for children that their wife has been sterilised are considered to want no more children. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] The number of living children includes one additional child if respondent's wife is pregnant (or if any wife is pregnant for men with more than one current wife).

6.3   IDEAL FAMILY SIZE

The discussion of fertility preferences earlier in this chapter focused on respondents' current childbearing preferences. These preferences are influenced by the number of children a respondent already has. The 2014 GDHS asked women and men age 15-49 about the total number of children they would like to have in their lifetime if they could choose the exact number when young and without children. Even though this question is based on a hypothetical situation, it provides two measures. First, for women and men who have not yet started a family, the data provide an idea of future fertility. Second, for older and high-parity women, the excess of past fertility over the ideal family size provides a measure of unwanted fertility.

Table 6.3 shows that only 2 percent of women and 1 percent of men were not able to provide a numeric response to the question asked to assess ideal family size.

Both women and men in Ghana prefer a big family, with only marginal differences between them: 4.3 children and 4.5 children are ideal for *all* women and men age 15-49, respectively, and 4.7 children and 5.1 children for *currently married women and men* age 15-49, respectively. The proportion of all women and men who want only one child is small (less than 1 percent for both women and men). Furthermore, only 8 percent of women and 11 percent of men want to have two children. By contrast, more than one-third of women (35 percent) and more than a quarter of men (27 percent) want to have four children.

There has been a slight increase in the mean ideal number of children among currently married women over the past six years, from 4.6 children in 2008 to 4.7 in 2014. Data in Table 6.3 also show that the mean ideal number of children increases with the number of living children, from 3.8 children among women with no children and 3.7 children for those with one child to 6.2 children among women with six or more children. The same pattern is observed among men. This positive association between actual and ideal number of children is due to two factors. First, to the extent that respondents are able to implement their fertility desires, those who want smaller families will tend to achieve smaller families. Second, some respondents may have difficulty admitting their desire for fewer children if they could begin childbearing again and may in fact report their actual number as their preferred number. Despite this tendency to rationalise, the data provide evidence of unwanted fertility.

Table 6.3 Ideal number of children by number of living children

Percent distribution of women and men 15-49 by ideal number of children, and mean ideal number of children for all respondents and for currently married respondents, according to the number of living children, Ghana 2014

[1] The number of living children includes current pregnancy for women.
[2] Means are calculated by excluding respondents who gave non-numeric responses.
[3] The number of living children includes one additional child if respondent's wife is pregnant (or if any wife is pregnant for men with more than one current wife).

Table 6.4 presents the mean ideal number of children for women age 15-49 by background characteristics. Data show that that the mean ideal number of children increases with age from 3.9 children among women age 15-24 to 5.3 children for women age 45-49. This pattern suggests a trend towards smaller family size. The ideal number of children is lower for women in urban than in rural areas (4.0 children and 4.7 children, respectively). Differences in the mean ideal number of children by region exist: the mean ideal number of children is highest among women in the Northern region (6.4 children) and lowest for women residing in the Greater Accra region (3.7 children).

The mean ideal number of children varies inversely with women's level of education and wealth. It decreases from 5.7 children for women with no education to 3.5 children for those with a secondary or higher education, and from 5.5 children for women in the lowest wealth quintile to 3.7 children for those in the highest quintile.

6.4 FERTILITY PLANNING

Information collected in the 2014 GDHS can also be used to estimate levels of unwanted fertility. This information provides some insight into the degree to which couples are able to control fertility. Women age 15-49 were asked a series of questions about each child born to them in the preceding five years, as well as about any current pregnancy, to determine whether the birth or pregnancy was wanted then (planned), wanted later (mistimed), or not wanted at all (unplanned) at the time of conception. In assessing these results, it is important to recognise that women may declare a previously unwanted birth or current pregnancy as wanted, and this rationalisation for a change in opinion results in an underestimate of the true extent of unwanted births.

Table 6.5 shows that 69 percent of all births in the five years preceding the survey were planned, 24 percent were mistimed, and 7 percent were unwanted.

The percentage of planned births has increased from 62 percent in the 2008 GDHS to 69 percent in the 2014 GDHS.

Table 6.5 shows that the proportion of wanted births is lowest for first order births (63 percent), it increases for births of the second and third order (75 percent each), and then it decreases again for births of the fourth or higher order (67 percent). The proportion of planned births is lowest for the youngest mothers under age 20 (42 percent) and highest among women age 25-39 (73-76 percent).

By contrast, mistimed births are more common among young mothers (under age 30) than among old mothers (above age 30). The percentage of unwanted births increases with mother's age at birth, from 1 percent among mothers under age 20 to 42 percent among those age 45-49.

6.5   WANTED FERTILITY RATES

The wanted fertility rate measures the potential demographic impact of avoiding unwanted births. It is calculated in the same manner as the total fertility rate but excludes unwanted births from the numerator. A birth is considered wanted if the number of living children at the time of conception is less than the ideal number of children reported by the respondent. The gap between wanted and actual fertility shows how successful women are in achieving their reproductive intentions. This measure also may be an underestimate to the extent that women may not report an ideal family size lower than their actual family size.

The total wanted fertility rates shows in Table 6.6 represent the levels of fertility that would have prevailed in the three years preceding the survey if all unwanted births had been avoided. Overall, Ghanaian women have 0.6 children more than their ideal number of 3.6 children. This implies that the total fertility rate (TFR) is 17 percent higher than it would be if unwanted births were avoided.

The gap between wanted and observed fertility rates is larger among women in rural areas (0.8 children) than among women in urban areas (0.3 children). By region, the gap is largest among women residing in the Central and Brong Ahafo region (0.9 children) and smallest among women in Western and Greater Accra regions (0.3 children each).

The gap between wanted and observed total fertility rates decreases with education. Women with no education have 0.7 children more than they want, compared with 0.3 children among women with a secondary or higher education. There is an inverse relationship between wanted fertility rates and wealth. The gap between wanted and actual fertility rates ranges from 0.2 children among women in the highest wealth quintile to 1.0 child among women in the second wealth quintile.

There has been a slight increase in the wanted fertility rate from 3.5 children in 2008 to 3.6 children in 2014.

Table 6.6 Wanted fertility rates

Total wanted fertility rates and total fertility rates for the three years preceding the survey, by background characteristics, Ghana 2014

Background characteristic	Total wanted fertility rates	Total fertility rate

> - Knowledge of contraception is universal in Ghana.
> - Twenty-seven percent of currently married women use contraception; 22 percent use a modern method.
> - The three most popular modern methods used by married women are injectables (8 percent), implants (5 percent), and the pill (5 percent).
> - Use of modern methods has more than quadrupled in the past 25 years, rising from 5 percent in 1988 to 22 percent in 2014.
> - The government sector remains the major source of contraceptives in Ghana, providing them for 64 percent of current users, an increase from 39 percent in 2008.
> - Overall, one in four contraceptive users discontinued using a method within 12 months of starting its use. Six percent of episodes of discontinuation occurred because of side effects or health concerns.
> - Thirty percent of currently married women have an unmet need for family planning services, with 17 percent having an unmet need for spacing and 13 percent having an unmet need for limiting.

Family planning has been a priority for the government of Ghana for many years. It is highlighted as a key factor in population management and national development outlined in the current Ghana Shared Growth and Development Agenda II: 2014-2017 (NDPC 2014). Important policy documents have been written to guide the implementation of the country's national family planning programme. These documents include the National Population Policy, the Reproductive Health Service Policy and Standard, the 2000 Adolescent Reproductive Health Policy, the Reproductive Health Commodity Security Strategy (2011-2016), the Draft National Condom and Lubricant Strategy and Market Segmentation Analysis for family planning, among others (MoH 2011).

The goal of family planning is to assist couples and individuals of reproductive age to achieve their reproductive goals and improve their general reproductive health. The objectives of Ghana's family planning programme are (1) to provide information, education, and counselling to individuals and couples, enabling them to decide freely and responsibly when to start childbearing and how to space the children they choose to have; (2) to provide affordable contraceptive services and make available a full range of safe and effective methods; and (3) to provide information on how to manage reproductive tract infections (RTIs) and sexually transmitted infections (STIs), including HIV and AIDS (GHS 2014).

Despite the high importance placed on family planning activities by national policies, strategies, and plans, adequate funding for the family planning programme remains a challenge, thereby affecting progress towards the set targets. In response, the government of Ghana has passed a law to include family planning in the National/District Health Insurance Scheme (N/DHIS). This will enhance the advocacy efforts of stakeholders in the area of reproductive health and family planning from the public and private sectors, civil society, nongovernmental organisations (NGOs), and development partners. However, the implementation of the law is yet to be realised.

This chapter presents information on knowledge of various contraceptive methods and discusses past and current prevalence. For users of rhythm or calendar method (periodic abstinence), knowledge of the ovulatory cycle is examined; for those relying on sterilisation, the age at the time of the procedure is assessed. Also discussed are the source of modern contraceptive methods, informed choice,

discontinuation rates and reasons, unmet need for family planning, nonuse of contraception, and intent to use contraceptive methods in the future. In addition, information is provided on exposure to family planning messages through the media and contact with family planning providers. These topics are of practical use to policymakers in formulating efficient and effective family planning strategies and policies. Although the main focus of this chapter is on women, results from the male survey are also presented because men play an important role in the realisation of reproductive goals. Comparisons are also made, where feasible, with findings from previous surveys to evaluate trends over the past years in Ghana.

7.1 KNOWLEDGE OF CONTRACEPTIVE METHODS

Acquiring knowledge about contraceptive methods is an important step towards gaining access to family planning services and adopting a suitable contraceptive method. The ability to recognise a family planning method when it is described is a simple test of a respondent's knowledge of the method but not necessarily an indication of the extent of his or her knowledge. The 2014 GDHS collected information on knowledge of contraception by asking respondents whether or not they had heard about eight modern methods (female and male sterilisation, intrauterine devices (IUDs), injectables, implants, the pill, male and female condoms, lactational amenorrhoea method (LAM), emergency contraception, and two traditional methods (rhythm and withdrawal). Respondents were also asked whether they knew of other methods in addition to those listed.

Table 7.1 shows the percentage of all women and men, currently married women and men, and sexually active unmarried women and men, age 15-49, who have heard of specific contraceptive methods. Knowledge of at least one method is nearly universal in Ghana, with 99 percent of women and men having this knowledge, regardless of their marital status. The high level of knowledge could be attributed to the successful dissemination of family planning messages, mainly through the mass media.

Table 7.1 Knowledge of contraceptive methods

Percentage of all respondents, currently married respondents, and sexually active unmarried respondents age 15-49 who know any contraceptive method, by specific method, Ghana 2014

Method		Women			Men	
	All women	Currently married women	Sexually active unmarried women[1]	All men	Currently married men	Sexually active unmarried men[1]

Number of respondents	na	na	na	4,388	2,290	432

na = Not applicable
[1] Had last sexual intercourse within 30 days preceding the survey

Modern methods are more widely known than traditional methods; almost all women (99 percent) know of a modern method, compared with 85 percent who know of a traditional method. Among modern methods, the male condom (96 percent), injectables (92 percent), the pill (91 percent), and female condoms

(87 percent) are the most commonly known modern methods among women. When compared with other modern methods, lactational amenorrhoea is known by a relatively small percentage of women (16 percent). Although about 7 in 10 women are aware about female sterilisation, just about one-third are aware about male sterilisation. Among traditional methods, rhythm and withdrawal are known by about three-quarters of all women (77 percent and 74 percent, respectively). The extent of and patterns in knowledge of modern and traditional methods of family planning among currently married and sexually active unmarried women are similar. However, sexually active unmarried women are substantially more aware about emergency contraception and traditional methods, particularly withdrawal compared with all women or currently married women.

Among all men age 15-49, 99 percent know of a modern method and 81 percent know of a traditional method. With respect to traditional methods, knowledge levels reflect the gender that has most control in the use of the method. While rhythm is more known among women than among men (77 percent versus 74 percent), withdrawal is known more among men than among women (77 percent versus 74 percent). Male condoms (99 percent), female condoms (88 percent), the pill (87 percent), and injectables (83 percent) are the most commonly known modern methods among men. Overall, knowledge of family planning methods is slightly higher among women than men; women know on average 8.5 contraceptive methods compared with an average of 8.2 methods for men.

Table 7.2 shows the percentage of currently married women and currently married men age 15-49 who have heard of at least one contraceptive method and who have heard of at least one modern method.

Table 7.2 Knowledge of contraceptive methods by background characteristics

[1] Female sterilisation, male sterilisation, pill, IUD, injectables, implants, male condom, female condom, lactational amenorrhoea method (LAM), emergency contraception, and other modern methods.

Knowledge of any method and of any modern method is almost universal among currently married women (100 percent and 99 percent, respectively) and men (100 percent each). There are only minor variations by background characteristics.

7.2 CURRENT USE OF CONTRACEPTION

This section presents information on the prevalence of current contraceptive use among women age 15-49 at the time of the survey. Level of current use is the most widely employed and valuable measure of the success of family planning programmes. The contraceptive prevalence rate (CPR) is usually defined as the percentage of currently married women who are currently using a method of contraception.

Table 7.3 shows the percent distribution of all women by age of currently married women, and sexually active unmarried women age 15-49 by contraceptive method currently used. Current use of any method is 23 percent among all women, 27 percent among currently married women, and 45 percent among sexually active unmarried women.

Among currently married women, 22 percent are using a modern method and 5 percent are using a traditional method. Contraceptive use varies with the woman's age. It is lowest among the youngest women age 15-19 (19 percent), mostly because they are in the early stages of family building, and oldest women age 45-49 (18 percent), some of whom are no longer fecund. Injectables are the most widely used modern method among currently married women (8 percent), followed by the implants and the pill (5 percent each).

Among sexually active unmarried women—most of whom are young—the most common methods are the male condom and the pill (8 percent each), followed by injectables and rhythm (7 percent each), and implants (5 percent). Use of a traditional method is notably higher among sexually active unmarried women (13 percent) than women who are currently married (5 percent).

7.3 CURRENT USE OF CONTRACEPTION BY BACKGROUND CHARACTERISTICS

Analysing current use of contraception by background characteristics is important because it helps identify subgroups of the population to target for family planning services. Table 7.4.1 shows the percent distribution of currently married women by their use of family planning methods, according to background characteristics. This table allows one to compare current contraceptive use across major population groups.

As mentioned earlier, more than one in four currently married women (27 percent) use some method of contraception, one in four (22 percent) use a modern method, and 5 percent a traditional method. Use of family planning methods increases with increasing number of children, from 21 percent for women with no living children to 30 percent for those with three or four children, and to 27 percent for women with five or more children. The same pattern is observed for use of most modern methods, with the exception of male condom use, which decreases with increasing parity. Use of a traditional method is highest among women with no children (7 percent) and lowest among those with five or more children (3 percent).

The prevalence of use of any method is similar among currently married women in urban and in rural areas (26 percent and 28 percent, respectively). By region, current use of any method is highest among women in Volta (32 percent) and lowest among women in Northern (11 percent).

Use of contraceptive methods increases with education from 19 percent for currently married women with no education to 34 percent of women with a secondary or higher education. Somewhat different patterns are observed for use of modern methods; their use is highest among women with primary education (27 percent) and lowest among women with no education (17 percent). There is no clear relationship between current contraceptive use and wealth.

To assess women's decision-making autonomy about family planning, the 2014 GDHS asked married women whether using contraception is mainly her decision, mainly her husband or partner's decision, or whether they both decided together. Data show that the majority of married women (63 percent) who are using contraception say that decisions about using family planning are made jointly by the husband and wife, over one-quarter (27 percent) of women say they alone make decisions about the use of family planning, and only 11 percent said that their husband/partner mainly decides about their use of contraception (data not shown).

Table 7.4.1 Current use of contraception by background characteristics

Percent distribution of currently married women age 15-49 by contraceptive method currently used, according to background characteristics, Ghana 2014

7.4   TRENDS IN CURRENT USE OF FAMILY PLANNING

Trends in current use of family planning can be used to monitor and evaluate the success of family planning programmes over time. Table 7.4.2 and Figure 7.1 show trends in modern contraceptive use among currently married women from 1988 to 2014. Data from six DHS surveys conducted in Ghana since 1988 show that contraceptive use among married women in Ghana has more than doubled, increasing from 13 percent in 1988 to 27 percent in 2014. The largest increase occurred in the decade between the 1988 and 1998 GDHS surveys (from 13 percent to 22 percent); current use has plateaued between 25 percent and 27 percent since the 2003 GDHS. Similarly, use of modern methods has more than quadrupled, from 5 percent in 1988 to 22 percent in 2014, with a notable increase from 17 percent to 22 percent in the past six years. Use of traditional methods has fluctuated since 1988, and has decreased somewhat over the past six years. The recent increase in modern contraceptive use is mostly due to more implants and fewer injectables.

Table 7.4.2 Trends in the current use of contraception

Percentage distribution of currently married women age 15-49 by contraceptive method currently used, according to several surveys

Method	GDHS 1988	GDHS 1993	GDHS 1998	GDHS 2003	GDHS 2008	GDHS 2014

Figure 7.1 Trends in current use of contraceptive methods, Ghana 1988-2014

Percentage of currently married women

□1988 ■1993 ■1998 ■2003 ■2008 ■2014
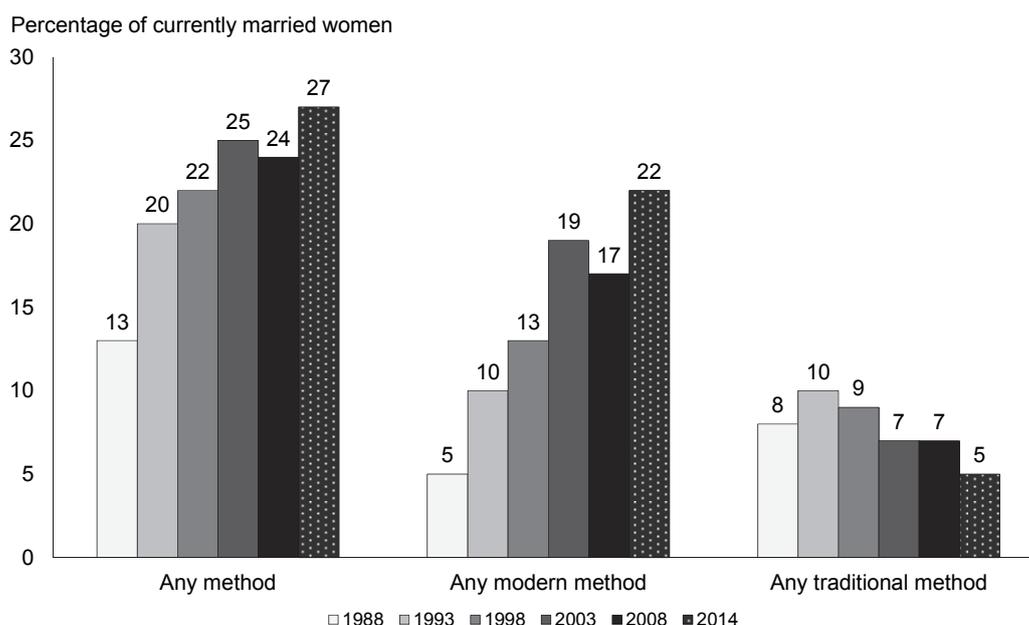

7.5   TIMING OF STERILISATION

The use of female sterilisation as a method of contraception is very low in Ghana, 1 percent among all women and 2 percent among currently married women age 15-49. Data show that the median age of sterilisation among women is 35.7 years. The majority of women perform the operation when they are age 35-39 (46 percent), followed by those in the 30-34 age group (28 percent; data not shown due to small numbers of sterilised women).

7.6   SOURCE OF MODERN CONTRACEPTION

Table 7.5 documents the main sources of contraception for users of selected modern methods. Such information is important for programme managers and implementers who design family planning policies and programmes. All current users of modern contraceptive methods were asked about the most recent source of their methods. The government sector remains the major source of contraceptive methods in Ghana, providing methods to 64 percent of current users, an increase from 39 percent in 2008. Within the government sector, the main sources are government hospitals or polyclinics (29 percent) and government health centres or clinics (25 percent).

One-third of users (33 percent) obtain their methods from the private medical sector, mostly from chemical or drug stores (22 percent) and pharmacies (7 percent). The percentage of users obtaining their methods from the private medical sector has decreased by from 51 percent in 2008 to 33 percent in 2014, due to the sharp decrease in the percentage who reported chemical or drug stores as their source (from 38 percent in 2008 to 22 percent in 2014).

Looking at specific methods, implants (94 percent), female sterilisation (92 percent), injectables (90 percent), and IUDs (84 percent) are obtained or performed mostly in public sector facilities. The National Reproductive Health Service Policy and Standards require that specialised providers administer different modern methods of family planning. These cadres of specialised providers are mostly available at a public sector health facility, which explains the large proportion of public sector users for these specific methods. On the other hand, more than 8 in 10 pill users (82 percent) and about 9 in 10 male condom users (89 percent) obtain their supply from the private medical sector, the majority from chemical or drug stores (64 percent and 61 percent, respectively) and from pharmacies (17 percent and 29 percent).

Although these findings point to the continued reliance on government facilities as a major source of contraceptives, the role of the private sector and the non-governmental sector cannot be ignored. To make family planning more accessible in hard to reach areas, the private sector should be encouraged to put in place the necessary systems to provide the full range of family planning methods.

Table 7.5 Source of modern contraception methods

Percent distribution of users of modern contraceptive methods age 15-49 by most recent source of method, according to method, Ghana 2014

7.7   BRANDS OF PILLS AND CONDOMS USED

To obtain information about use of social marketing brands of pills and condoms in Ghana, women who were using the pill and the male condom at the time of the survey were asked about the brands that they used the last time. This information is useful for monitoring the success of social marketing programmes. Among pill users, the most common brands used are secure (67 percent) and N/M tablets (15 percent). Use of the brands varies according to residence, educational level, and wealth quintile. Among the male condom users, the most commonly used brands are Champion (24 percent), Gold cycle (12 percent), Be Safe, no logo (7 percent), and Panther (5 percent; data not shown).

7.8   INFORMED CHOICE

Informed choice is an important tool for assessing, monitoring and evaluating the quality of family planning services. Family planning clients have a right to information about their choice of contraceptive method. Providers are required to inform all users of contraceptive methods about 1) the potential side effects of their method, 2) what they should do if they experience side effects or signs of a problem, and 3) alternate methods of family planning they can use. Current users of modern methods of contraception were asked whether they were informed about the possible side effects or problems they might have with using a method, what to do if they experienced side effects, and other methods they could use. This information assists users in coping with side effects and decreases unnecessary discontinuations. Moreover, such data serve as a measure of the quality of family planning service provision. Table 7.6 presents the results by type of method and source.

About 7 in 10 modern contraceptive users (67 percent) were informed by a health or family planning worker about potential side effects of the method they use, about 6 in 10 (57 percent) were informed about what to do if they experienced side effects, and 7 in 10 (72 percent) were informed of other available methods of contraception. Looking at the type of method, women using the pill and female sterilisation are the least likely to be provided with informed choices compared with users of the other methods (53 percent and 51 percent, respectively).

Users are less likely to receive information about side effects or problems of the method used from a private than a public medical facility (37 percent versus 77 percent), or information about what to do if they experienced side effects (28 percent versus 67 percent), or about other methods that could be used (48 percent versus 81 percent).

Table 7.6 Informed choice

Among current users of modern methods age 15-49 who started the last episode of use within the five years preceding the survey, the percentage who were informed about possible side effects or problems of that method, the percentage who were informed about what to do if they experienced side effects, and the percentage who were informed about other methods they could use, by method and initial source, Ghana 2014

7.9 CONTRACEPTIVE DISCONTINUATION RATES

Couples can realise their reproductive goals only when they consistently and correctly use contraceptive methods. A prominent concern for family planning programmes is the rate at which contraceptive users discontinue using their methods. In the "Calendar" section of the Woman's Questionnaire, all segments of contraceptive use from 3-59 months prior to the survey are recorded. The month of interview and the two months prior to the survey are ignored in order to avoid the bias that may be introduced by unrecognised pregnancies. One-year contraceptive discontinuation rates based on the calendar data are presented in Table 7.7.

Overall, 25 percent of the episodes of contraceptive use were discontinued within 12 months of starting its use for any reason. Six percent of episodes of discontinuation occurred because of fear of side effects or health concerns, 5 percent each occurred because of desire to become pregnant or other fertility-related reasons, and 4 percent were attributed to method failure (became pregnant while using).

Discontinuation rates also vary by method. Rates are highest for the male condom (35 percent), the pill (30 percent), and injectables (29 percent).

Table 7.7 Twelve-month contraceptive discontinuation rates

Among women age 15-49 who started an episode of contraceptive use within the five years preceding the survey, the percentage of episodes discontinued within 12 months, by reason for discontinuation and specific method, Ghana, 2014

Method	Method failure	Desire to become pregnant	Other fertility-related reasons[2]	Side effects/ health concerns	Wanted more effective method	Other method-related reasons[3]	Other reasons	Any reason[4]	Number of episodes of use[5]
Pill	6.0	4.7	5.8	7.6	0.7	3.3	1.5	29.6	585
Injectables	1.5	6.0	2.4	13.1	1.4	1.6	3.0	29.1	862
Implants	0.5	0.7	0.0	4.9	0.0	0.7	0.0	6.9	369
Male condom	1.7	5.6	17.9	0.7	0.8	3.5	4.8	35.1	279
Rhythm	10.5	4.4	2.9	0.0	0.2	0.3	0.4	18.8	398
Withdrawal	(6.9)	(2.7)	(5.5)	(0.0)	(5.0)	(0.0)	(0.7)	(20.8)	182
All methods[1]	4.2	4.5	5.1	6.3	1.0	1.9	1.7	24.7	2,960

Note: Figures are based on life table calculations using information on episodes of use that began 3-62 months preceding the survey. Figures in parentheses are based on 25-49 unweighted cases.
[1] Includes female sterilisation, male sterilisation, IUD, female condom, diaphragm, foam/jelly, and LAM.
[2] Includes infrequent sex/husband away, difficult to get pregnant/menopausal, and marital dissolution/separation
[3] Includes lack of access/too far, costs too much, and inconvenient to use
[4] Reasons for discontinuation are mutually exclusive and add to the total given in this column.
[5] Number of episodes of use includes both episodes of use that were discontinued during the period of observation and episodes of use that were not discontinued during the period of observation.

7.10 REASONS FOR DISCONTINUATION OF CONTRACEPTIVE USE

Another perspective on discontinuation of modern contraceptive use is provided in Table 7.8, which shows the percent distribution of discontinuations of contraceptive methods in the five years preceding the survey by reasons for discontinuation, according to specific method.

Table 7.8 Reasons for discontinuation

Percent distribution of discontinuations of contraceptive methods in the five years preceding the survey by main reason stated for discontinuation, according to specific method, Ghana 2014

Reason	Pill	Injection	Implants	Rhythm	With-drawal	Other[1]	All methods
Became pregnant while using	22.0	7.0	8.1	45.8	40.1	28.5	20.4
Wanted to become pregnant	28.0	30.1	21.7	32.1	17.6	18.5	27.2
Husband disapproved	3.1	2.1	1.7	1.5	4.5	0.0	2.7
Wanted a more effective method	2.0	2.7	1.7	5.2	11.8	5.3	3.7
Side effects/health concerns	20.7	39.2	55.4	0.5	0.0	9.3	21.6
Lack of access/too far	4.4	1.1	0.0	0.0	0.0	0.0	1.5
Cost too much	1.7	1.8	1.1	0.0	0.0	0.0	1.2
Inconvenient to use	1.5	1.6	4.8	0.4	0.0	6.3	2.1
Up to God/fatalistic	0.1	0.0	0.0	0.7	0.0	0.0	0.2
Difficult to get pregnant/menopausal	0.4	0.1	0.0	0.0	0.0	0.0	0.1
Infrequent sex/husband away	13.9	9.5	4.9	12.3	20.9	32.0	16.3
Marital dissolution/separation	0.2	0.5	0.0	0.4	3.4	0.0	0.6
Other	1.9	4.3	0.7	1.0	1.6	0.0	2.5
Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Number of discontinuations	405	541	89	292	96	84	1,702

[1] Includes female sterilisation, IUD, diaphragm, foam/jelly, and lactational amenorrhoea method (LAM)

The most common reasons for discontinuing a method are that the woman wanted to become pregnant (27 percent), experiencing side effects or having health concerns (22 percent), becoming pregnant while using (20 percent), and infrequent sex or husband away (16 percent). The main reasons for discontinuing use of injectables and implants is experiencing side effects or having health concerns (39 percent and 55 percent, respectively), followed by desire to become pregnant (30 percent and 22 percent,

respectively). Among pill users who discontinued method use, the main reason for discontinuation is desire to become pregnant (28 percent), followed by method failure (22 percent) and experiencing side effects or having health concerns (21 percent). Becoming pregnant while using a method (method failure) was the predominate reason for discontinuing rhythm and withdrawal methods (46 percent and 40 percent, respectively).

7.11 KNOWLEDGE OF FERTILE PERIOD

A basic knowledge of reproductive physiology provides a useful background for the successful practice of the rhythm method. Seventy seven percent of married women have heard of the rhythm method, but only 3 percent are currently using the method as shown in Table 7.1 and Table 7.3. Women's knowledge about the time during the menstrual cycle when a woman is most likely to get pregnant is shown in Table 7.9.

Overall, only 36 percent of women age 15-49 correctly reported the most fertile time as being halfway between two menstrual periods. Among users of the rhythm method who rely on accurate knowledge of the fertile method, only about half (54 percent) were able to correctly identify a woman's monthly cycle; 36 percent incorrectly reported that a woman's most fertile period is directly after menstruation has ended. A lower proportion of nonusers of the rhythm method (36 percent) have correct knowledge of a woman's most fertile period. These results indicate a sustained need for education about women's physiology of reproduction and effective use of contraceptive methods.

Table 7.9 Knowledge of fertile period

Percent distribution of women age 15-49 by knowledge of the fertile period during the ovulatory cycle, according to current use of the rhythm method, Ghana 2014

Perceived fertile period	Users of rhythm method	Nonusers of rhythm method	All women
Just before her menstrual period begins	2.8	8.1	7.9
During her menstrual period	1.7	2.5	2.5
Right after her menstrual period has ended	36.4	35.4	35.4
Halfway between two menstrual periods	54.2	35.7	36.3
No specific time	2.9	8.6	8.5
Don't know	2.0	9.7	9.4
Total	100.0	100.0	100.0
Number of women	289	9,107	9,396

7.12 NEED AND DEMAND FOR FAMILY PLANNING SERVICES

Data in this section provide information on the extent of need and potential demand for family planning services in Ghana. Currently married or sexually active fecund women who want to postpone their next birth for two or more years or who want to stop childbearing altogether but are not using a contraceptive method are considered to have an unmet need for family planning. Pregnant women are considered to have an unmet need for spacing or limiting if their pregnancy was mistimed or unwanted. Similarly, amenorrhoeic women who are not using family planning and whose last birth was mistimed are considered to have an unmet need for spacing, and those whose last child was unwanted have an unmet need for limiting. Women who are currently using a family planning method are said to have a met need for family planning. Total demand for family planning services comprises those who fall in the met need and unmet need categories.

Table 7.10 shows the need and demand for family planning among currently married women by background characteristics. Thirty percent of currently married women have an unmet need for family planning, 17 percent have an unmet need for spacing, and 13 percent have an unmet need for limiting. Twenty-seven percent of women have a met need for family planning, i.e., they are using a method, 15 percent for spacing, and 12 percent for limiting their births. If all currently married women who say they

want to space or limit their children were to use a family planning method, the contraceptive prevalence rate would increase from 27 percent to 57 percent.

Table 7.10 Need and demand for family planning among currently married women

Percentage of currently married women age 15-49 with unmet need for family planning, percentage with met need for family planning, the total demand for family planning, and the percentage of the demand for contraception that is satisfied, by background characteristics, Ghana 2014

Background characteristic	Unmet need for family planning			Met need for family planning (currently using)			Total demand for family planning[1]			Percentage of demand satisfied[2]	Percentage of demand satisfied by modern methods[3]	Number of women
	For spacing	For limiting	Total	For spacing	For limiting	Total	For spacing	For limiting	Total			
Age

Note: Numbers in this table correspond to the revised definition of unmet need described in Bradley et al., 2012.
[1] Total demand is the sum of unmet need and met need.
[2] Percentage of demand satisfied is met need divided by total demand.
[3] Modern methods include female sterilisation, male sterilisation, pill, IUD, injectables, implants, male condom, female condom, diaphragm, foam/jelly, and lactational amenorrhoea method (LAM)

Table 7.10 further shows that only 47 percent of the family planning needs of married women are currently being met; 39 percent of the demand for family planning is satisfied by modern methods.

Total unmet need for family planning is highest among the youngest women age 15-19 (51 percent) and lowest among the oldest women age 45-59 (14 percent). Unmet need is only slightly higher in rural than in urban areas (31 percent versus 29 percent). By region, unmet need ranges from 36 percent in Volta to 27 percent in Western, Brong Ahafo, and Upper East regions. Unmet need is lowest among women with a secondary or higher education (24 percent) and women in the highest wealth quintile (25 percent) when compared with women with other levels of education and wealth.

Total demand for family planning is highest among women age 15-19 (69 percent) and lowest among those age 45-49 (33 percent). Demand for family planning is highest among rural women (59 percent), women in Volta (69 percent), those with primary or middle/JSS/JHS education (60-61 percent), and women in the middle three quintiles (59-60 percent). The percentage of women whose demand for family planning is satisfied by modern methods is highest among those age 45-49 (48 percent), those living

in rural areas (42 percent), women in Upper West and Upper East (47 percent each), those with primary education (44 percent), and women in the middle or second wealth quintile (41-42 percent).

To better understand the underlying factors behind observed variations in unmet need and to strengthen assessments of the demand for family planning, a follow up study on family planning was conducted by a different team on a subsample of households selected for the GDHS survey. The research team re-interviewed a subsample of the selected GDHS original female respondents in 13 clusters who consented to be re-interviewed. Women age 15-44 who were not currently using family planning or who reported not wanting their current pregnancy or their most recent live birth were eligible for the follow-up survey. Additionally, a randomly selected 10 percent of current female users of family planning age 15-44 in those clusters also were eligible for the study. Results of the follow up study on unmet need for family planning are not discussed in this report and will be published in a separate report.

Figure 7.2 shows the trend of unmet need and percentage of demand satisfied with modern methods from 1993 to 2014. Unmet need declined from 37 percent in 1993 to 35 percent in 2003, increased to 36 percent in 2008, before decreasing thereafter, to 30 percent in 2014. This trend was reversed for the demand satisfied by modern methods, an indication that, modern methods contribute substantially to the use of contraception by married women.

Figure 7.2 Trends in unmet need and percentage of demand satisfied with modern methods, Ghana 1993-2014

Percentage of currently married women

□ 1993 ■ 1998 ■ 2003 ■ 2008 ■ 2014
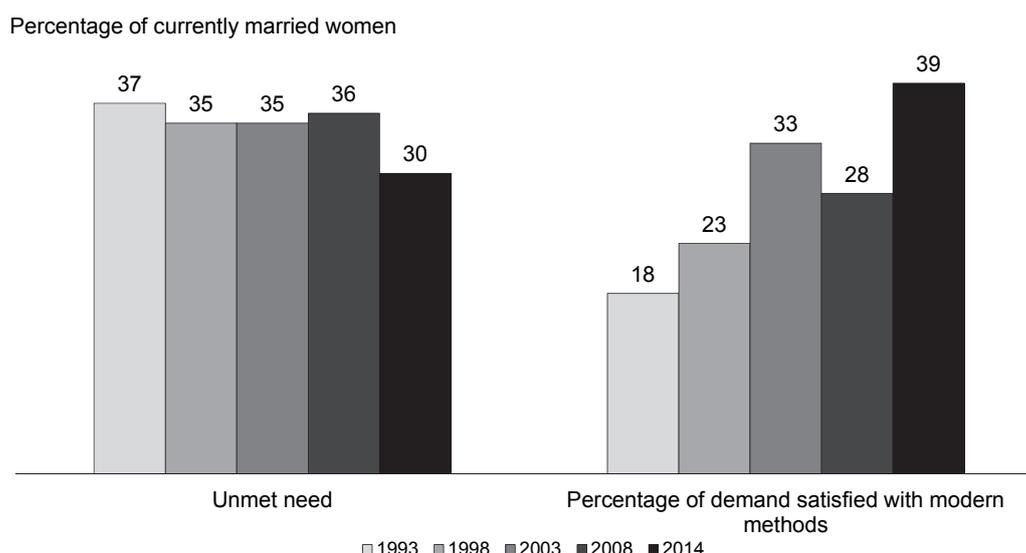

Note: Data on unmet need not available for the 1988 GDHS survey. The unmet need estimates for the 1993, 1998, 2003, and 2008 GDHS surveys have been recalculated using the revised definition of unmet need (Bradley et al., 2012).

7.13 FUTURE USE OF CONTRACEPTION

An important indicator of the changing demand for family planning is the extent to which nonusers plan to use contraceptive methods in the future. In the 2014 GDHS, women age 15-49 who were not using any contraceptive method at the time of the survey were asked about their intention to use family planning in the future. Table 7.11 shows that, among currently married women not using contraception, 36 percent intend to use a family planning method in the future, 6 percent are unsure of their intentions, and 58 percent have no intention of using any method in the future.

The proportion of women who are not using a method but intend to do so in the future is lowest among women with no children (26 percent) when compared with women with one or more children (36-38 percent).

Table 7.11 Future use of contraception

Percent distribution of currently married women age 15-49 who are not using a contraceptive method by intention to use in the future, according to number of living children, Ghana 2014

| | Number of living children[1] | | | | | |
Intention	0	1	2	3	4+	Total
Intends to use	26.3	35.7	37.7	37.6	35.7	35.9
Unsure	12.7	5.2	5.5	6.5	5.1	5.9
Does not intend to use	61.1	59.0	56.8	55.9	59.1	58.1
Total	100.0	100.0	100.0	100.0	100.0	100.0
Number of women	229	565	815	722	1,571	3,902

Note: Totals may not add up to 100 percent because women with missing information are not shown separately.
[1] Includes current pregnancy

7.14 EXPOSURE TO FAMILY PLANNING MESSAGES

The media play an important role in communicating messages about family planning. Data on level of exposure to such media as radio, television, and printed materials are important for programme managers and planners to effectively target population subgroups for information, education, and communication campaigns. To assess the extent to which the media serve as a source of family planning messages, respondents were asked whether they had heard or seen a message about family planning on the radio or television, or in the print media (newspapers and magazines), in the past few months preceding the survey. The results are shown in Table 7.12.

Radio is the most common source of family planning messages for both women (57 percent) and men (67 percent). Approximately half of respondents (51 percent of women and 57 percent of men) saw a family planning message on the television. Newspapers and magazines are the least common source of family planning messages for both women and men (7 percent and 14 percent, respectively).

Exposure to family planning messages is more common among men than women; roughly one in three women (34 percent) and one in four men (26 percent) were not exposed to any family planning messages in the three media. Youngest respondents age 15-19 have the lowest exposure to family planning messages though the media; 50 percent of women and 41 percent of men in this age group have not heard or seen any family planning messages in any of the three media in the past few months. Exposure to family planning messages through the media is more common in urban areas than in rural areas. Among women, exposure to family messages through television is higher in Greater Accra (76 percent) and lowest in Upper East (16 percent). Among men, it is highest in Ashanti (78 percent) and lowest in Northern (30 percent). Exposure to family planning through the various media increases with the level of education and wealth quintile for both women and men.

Table 7.12 Exposure to family planning messages

Percentage of women and men age 15-49 who heard or saw a family planning message on radio, on television or in a newspaper or magazine in the past few months, according to background characteristics, Ghana 2014

7.15 CONTACT OF NONUSERS WITH FAMILY PLANNING PROVIDERS

When family planning providers visit women in the field or when women visit health facilities, service providers are expected to discuss reproductive health needs and contraceptive options available, and to counsel women to adopt a method of family planning. To get insight into the level of contact between nonusers and health workers, women who were not using contraception were asked whether a fieldworker had visited them during the 12 months preceding the survey and discussed family planning. In addition, women were asked whether they had visited a health facility in the 12 months preceding the survey for any reason and whether anyone at the facility had discussed family planning with them during the visit.

Table 7.13 shows that fieldworkers discussed family planning with 10 percent of nonusers during the 12 months preceding the survey. At the same time, 16 percent of nonusers visited a health facility and discussed family planning at the facility. About one in three women (32 percent) visited a health facility but did not discuss family planning. The level of contact of nonusers with family planning providers varies by background characteristics. Overall, 77 percent of women who could have been exposed to family

planning information did not discuss family planning during a field visit or at a health facility, indicating numerous missed opportunities to inform and educate women about family planning.

Women in the youngest and oldest age groups are the least likely to discuss family planning with a service provider (5 percent each) than other women. The proportion of women not using family planning and who did not discuss family planning with a fieldworker or service provider at a health facility in the past few months is higher among women in urban areas (80 percent), women in Western region (85 percent), and among women with a secondary or higher education (80 percent). These results may indicate that some groups of women are already using contraceptive methods, or that they already have information about family planning and, therefore, do not feel the need to discuss family planning issues with providers, or they may be less likely to have visited a facility.

Table 7.13 Contact of nonusers with family planning providers

Among women age 15-49 who are not using contraception, the percentage who during the past 12 months were visited by a fieldworker who discussed family planning, the percentage who visited a health facility and discussed family planning, the percentage who visited a health facility but did not discuss family planning, and the percentage who did not discuss family planning either with a fieldworker or at a health facility, by background characteristics, Ghana 2014

Background characteristic	Percentage of women who were visited by fieldworker who discussed family planning	Percentage of women who visited a health facility in the past 12 months and who:		Percentage of women who did not discuss family planning either with fieldworker or at a health facility	Number of women
		Discussed family planning	Did not discuss family planning

7.16 ATTITUDES TOWARDS FAMILY PLANNING AMONG MEN

The 2014 GDHS assessed male respondent's attitudes towards contraception by asking men age 15-59 whether they agreed or disagreed with two statements about family planning use: 1) contraception is women's business and a man should not have to worry about it; and 2) women who use contraception may become promiscuous. The results on attitudes towards family planning show that the majority of Ghanaian men age 15-59 think that men should take some responsibility towards family planning, with 73 percent of men rejecting the statement that contraception is a woman's business and that men should not have to

worry about it. However, 24 percent of men agree with the statement, and 4 percent say they don't know (data not shown).

Regarding the statement that women who use contraception may become promiscuous, 46 percent of men agree with the statement and 49 percent disagree, and 5 percent of men said that they don't know (data not shown).

In the 2003 GDHS, data on men's attitudes towards contraception were based on all men age 15-59 who know a method of family planning, while in the 2008 GDHS data were based on currently married men age 15-49 regardless of knowledge of a family planning method, and in 2014 GDHS data are based on all men age 15-59. To compare the three surveys, the 2014 and 2008 GDHS data on men's attitudes towards contraception were re-calculated to be similar to those in the 2003 GDHS report. The results indicate that between 2003 and 2014, there has been a decline in the proportion of men age 15-59 who know a method of family planning and agree with the statement that contraception is women's business (35 percent in 2003, compared with 20 percent in 2008 and 24 percent in 2014). There has been a smaller decrease in the proportion of men who agree with the statement that women who use contraception may become promiscuous (53 percent in 2003, compared with 47 percent in 2008 and 46 percent in 2014; data not shown).

INFANT AND CHILD MORTALITY

8

┌───┐
Key Findings:

- Infant mortality rate is 41 deaths per 1,000 live births and under-5 mortality is slightly higher at 60 deaths per 1,000 live births. At these levels, one in every 24 Ghanaian children dies before reaching age 1, and one in every 17 does not survive to his or her fifth birthday.
- Infant mortality has declined by 28 percent since 1998, while under-5 mortality has declined by 44 percent over the same period.
- Under-5 mortality is highest in the Northern, Upper West, and Ashanti regions of Ghana.
- The neonatal mortality rate for the preceding five years is 29 deaths per 1,000 live births, 2.2 times the postneonatal rate.
- The perinatal mortality rate for the same reference period is 38 deaths per 1,000 pregnancies.
└───┘

This chapter describes levels, trends, and differentials in early childhood mortality and high-risk fertility behaviour of women in Ghana. Infant and child mortality rates are important indicators of a country's socioeconomic development and quality of life as well as its health status. Measures of childhood mortality also contribute to a better understanding of the progress of population and health programmes and policies. Analyses of mortality measures are useful in identifying promising directions for health and nutrition programmes and improving child survival efforts in Ghana. Disaggregation of mortality measures by socioeconomic and demographic characteristics helps to identify differentials in population subgroups and target high-risk groups for effective programmes. Measures of childhood mortality are also useful for population projections.

Childhood mortality in general and infant mortality in particular are often used as broad indicators of social development or as specific indicators of health status. Childhood mortality rates are used to monitor a country's progress towards Millennium Development Goal 4, which aims for a two-thirds reduction in the under-five mortality rate by the year 2015 (United Nations 2000). Results from the 2014 GDHS can be used in monitoring the impact of major national neonatal and child health interventions, strategies, and policies such as the Under-5 Child Health Policy 2007 – 2015, which is intended to reduce under-5 mortality from 111 deaths per 1,000 live births (GDHS 2003) to 40 deaths per 1,000 live births by 2015.

Neonatal, postneonatal, infant, child, and under-5 mortality rates are calculated from birth and death data derived from vital registration forms or from household surveys. The reliability of mortality estimates depends on the accuracy and completeness of reporting and recording of births and deaths. Underreporting and misclassification are common, especially for deaths occurring early in life.

The 2014 GDHS provides various measures of mortality. The mortality rates presented in this chapter are computed from information gathered in the birth history section of the Woman's Questionnaire. Women age 15-49 were asked whether they had ever given birth. Those who had ever given birth were asked to report the number of sons and daughters living with them, the number living elsewhere, and the number who had died. Women were also asked for the number of births they had that did not end in a live birth. A detailed history of all births was gathered in chronological order starting with the first birth. Women were asked whether a birth was single or multiple, the sex of the child, the date of birth (month and year), survival status, the age of the child on the date of the interview if alive, and, if not alive,

the age at death of each child born alive. Because the primary causes of childhood mortality change as children age—from biological factors to environmental factors—childhood mortality rates are expressed by age categories and are customarily defined as follows:

- **Neonatal mortality (NN):** the probability of dying within the first month of life

- **Postneonatal mortality (PNN):** the difference between infant and neonatal mortality

- **Infant mortality ($_1q_0$):** the probability of dying between birth and the first birthday

- **Child mortality ($_4q_1$):** the probability of dying between exact ages 1 and 5

- **Under-5 mortality ($_5q_0$):** the probability of dying between birth and the fifth birthday

Rates of childhood mortality are expressed as deaths per 1,000 live births, except in the case of child mortality, which is expressed as deaths per 1,000 children surviving to age 1.

Information on stillbirths and deaths that occur within seven days of birth is used to estimate perinatal mortality, which is the number of stillbirths and early neonatal deaths per 1,000 stillbirths and live births.

8.1   ASSESSMENT OF DATA QUALITY

As with all indicators in the GDHS, the accuracy of early childhood mortality estimates is influenced by two factors: sampling error and nonsampling error. Sampling error is inherent in the survey because the sample for the GDHS was only one of many samples that could have been selected for the survey. As described further in Appendix B, the sampling error associated with the GDHS mortality data can be evaluated statistically to provide an estimate of the range within which the actual mortality rates in Ghana lie.

Nonsampling error arises from problems occurring during the collection or processing of mortality data. Specifically, the reliability of the mortality estimates depends upon full reporting of children who die, the absence of differential displacement of birth dates of surviving and dead children, and accurate information on ages at death. Although the nonsampling error associated with the GDHS mortality data cannot be evaluated statistically, Appendix C includes several tables that can be used to assess the extent to which the GDHS mortality data may be subject to common reporting errors.

A common data quality problem may arise from errors in the reporting of birth dates. Displacement of births can affect the accuracy of mortality trends if they result in deaths being transferred from one time period to another, e.g., from the period 0 to 4 years to the period 5 to 9 years before the survey. Displacement may result from recall problems among mothers. However, it also may reflect deliberate transference of births from one period to another by interviewers interested in reducing their workload; they avoid the detailed set of maternal and child health questions included in DHS surveys for births occurring in the last five years. An examination of the distribution of the 2014 GDHS birth history data by calendar year shows no evidence of major transference of births from 2009 to previous years (Table C.4).

Omission, or failure to report births that did not survive, can lead to serious underestimation of mortality, if severe. Omission, which can be difficult to detect, is assumed to occur most often for deaths in early infancy and to increase for time periods more remote from the survey. One approach in looking for evidence of omission is to compare the ratio of neonatal deaths to all infant deaths before the survey and the ratio of early neonatal deaths (deaths in the first week of life) to all neonatal deaths to see if these measures fall within expected ranges.

Examination of the 2014 GDHS infant death data shows that the proportion of neonatal to infant deaths ranges from 71 percent in the period 0 to 4 years prior to the survey to 60 percent during the period 15 to 19 years before the survey (Table C.6). This pattern conforms to the expectation that, as mortality levels decline, a larger proportion of infant deaths will take place during the early neonatal period. Table C.5 shows data on age at death for early infant deaths. Selective underreporting of early neonatal deaths would result in an abnormally low ratio of deaths within the first seven days of life to all neonatal deaths. Early neonatal deaths do not appear to be underreported; the ratio of early neonatal deaths to all neonatal deaths is 88 percent in the period 0 to 4 years prior to the survey. Over time, the figures vary within a narrow range for the 20 years preceding the survey, suggesting no selective omission of early infant deaths.

Another potential data quality problem is heaping of the age at death. Errors in the reporting of the age at death may result in the transference of deaths from one age bracket for which mortality rates are being calculated to another. For example, heaping on age 1 year or 12 months can result in an underestimate of the infant mortality rate and an overestimate of the child mortality level. Several steps were taken in the training of the GDHS interviewers and in the structuring of the GDHS birth history to reduce errors in reporting the age at death. Interviewers were instructed to record age at death in days if the child died during the first month of life. They were to record age at death in months if the child died in the first two years of life. Because heaping on "1 year" or "12 months" is very common, interviewers were asked specifically to probe when the mothers gave these responses. The distribution of deaths under two years during the 20 years prior to the survey by age at death in months shows that there is heaping at age 12 months during any of the periods before the survey, with corresponding deficits in adjacent months. Table C.6 shows that there are 123 reported deaths at 12 months compared with 13 deaths at 11 months, 0 deaths at 13 months and 3 deaths at 14 months. This is likely to slightly underestimate infant mortality and overestimate child mortality, however this will not have any effect on the mortality estimates for the period 0 to 4 years before the survey since heaping of deaths at age 12 months is much less pronounced in the most recent period of 0 to 4 years prior to the survey (10 deaths) than in the periods of 5-9 years and 10-14 years prior the survey (40-43 deaths).

In addition to recall errors for the more distant retrospective periods, there are structural reasons for limiting mortality estimation to recent periods, preferably to the periods 0-4, 5-9, and 10-14 years before the survey. In fact, except for the first period (0-4 years), the other periods have slightly biased estimates because they are based on the child mortality experiences of women age 15-44 and 15-39, respectively, instead of women age 15-49 as in the period 0-4 years preceding the survey. Therefore, estimating mortality for periods more than 10-14 years before the survey is not advisable.

In summary, while there is evidence of some omission or displacement of infant deaths from one period to another, infant deaths in the 2014 GDHS do not appear to be severely underreported.

8.2   LEVELS AND TRENDS IN INFANT AND CHILD MORTALITY

Table 8.1 presents neonatal, postneonatal, infant, child, and under-5 mortality rates for three five-year periods preceding the survey. Neonatal mortality in the most recent period (2009-2014) is 29 deaths per 1,000 live births. This rate is 2.2 times the postneonatal rate (13 deaths per 1,000 live births) during the same period. Therefore, the risk of dying for any Ghanaian child who survives the first month of life is reduced by more than half (i.e., 55 percent) in the remaining 11 months of the first year of life. During the same period, the infant mortality rate was 41 deaths per 1,000 live births, the child mortality rate was 19 deaths per 1,000 children surviving to age 12 months, and the overall under-5 mortality rate was 60 deaths per 1,000 live births. Sixty-eight percent of all deaths among children under age 5 in Ghana take place before a child's first birthday, with 48 percent occurring during the first month of life. This means that one in every 24 children in Ghana dies before reaching age 1, while one in every 17 does not survive to her or his fifth birthday.

Table 8.1 Early childhood mortality rates

Neonatal, postneonatal, infant, child, and under-5 mortality rates for five-year periods preceding the survey, Ghana 2014

Years preceding the survey	Neonatal mortality (NN)	Postneonatal mortality (PNN)[1]	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-5 mortality ($_5q_0$)
0-4	29	13	41	19	60
5-9	33	21	54	28	81
10-14	30	22	52	37	87

[1] Computed as the difference between the infant and neonatal mortality rates

Mortality trends can be examined in two ways: by comparing mortality rates for three five-year periods preceding a single survey and by comparing mortality estimates obtained from various surveys. However, comparisons between surveys should be interpreted with caution because of variations in quality of data, time references, and sample coverage. In particular, sampling errors associated with mortality estimates are large and should be taken into account when examining trends between surveys.

Data from the 2014 GDHS show that neonatal mortality has declined marginally by 3 percent over the 15-year period preceding the survey, from 30 to 29 deaths per 1,000 live births. The corresponding declines in postneonatal, infant, and under-5 mortality over the 15-year period are 41 percent, 21 percent, and 31 percent respectively.

8.2.1 Childhood Mortality Trends 1988-2014

The 2014 GDHS documents a pattern of decreasing under-5 mortality during the 15 years prior to the survey. Results from the six GDHS surveys conducted between 1988 and 2014 show a similar decline in childhood mortality over the past two and a half decades (Figure 8.1). This decline is especially pronounced over the past decade. For example, the infant mortality rate declined from 64 per 1,000 live births for the five-year period preceding the 2003 GDHS to 41 per 1,000 live births during the same period prior to the 2014 GDHS. Similarly, the under-5 mortality rate decreased from 111 per 1,000 live births for the five-year period preceding the 2003 GDHS to 60 per 1,000 live births during the same period prior to the 2014 GDHS.

Overall, infant mortality has declined by 47 percent since 1988, from 77 deaths per 1,000 live births in 1983-1987 to 41 per 1,000 live births in 2010-2014. An even more impressive decline was observed in under-5 mortality, which decreased by 61 percent from 155 deaths per 1,000 live births to 60 deaths per 1,000 live births over the same period. The data also show declines of 29 percent and 50 percent in neonatal and postneonatal mortality, respectively, since 1993. An examination of neonatal, infant, and under-5 mortality rates in Ghana since 1998 reveals that neonatal mortality has decreased at a slower pace than infant and child mortality. This has resulted in an increase in the contribution of neonatal deaths to infant deaths from 53 percent in 1998 to 71 percent in 2014. Similarly the contribution of neonatal deaths to under-5 mortality also increased from 28 percent of under-5 deaths to 48 percent over the same period.

Figure 8.1 Mortality trends, Ghana 1988-2014

Deaths per 1,000 live births

Mortality rate

□ 1983-1987   □ 1989-1993   ▨ 1994-1998   ■ 1999-2003   ■ 2004-2008   ■ 2010-2014
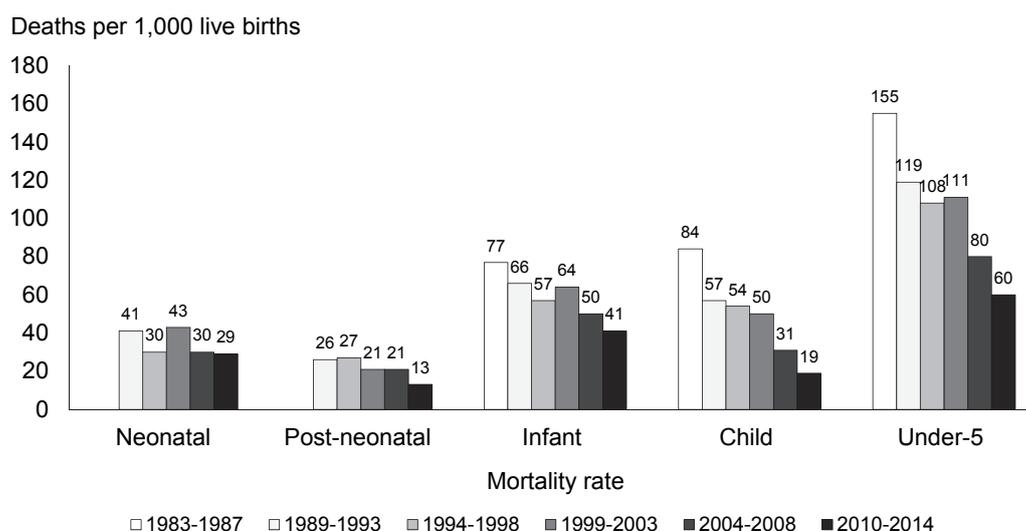

8.2.2   Recent Trends 2008-2014

It must be noted that since 2008 there has been only a marginal decline (3 percent) in neonatal mortality compared with 38 percent, 18 percent, and 25 percent declines in postneonatal, infant, and under-5 mortality over the same period. This is happening against the background of the implementation of the Health Sector Medium-Term Development Plan 2010-2013, which is part of the Ghana Shared Growth and Development Agenda 2010-2013. Also ongoing is the nationwide Child Health Policy 2007-2015 with the target of reducing neonatal mortality from 43 deaths per 1,000 live births (2003 GDHS) to 25 deaths per 1000 live births by 2015 in an effort to address Millennium Development Goal 4. Since the 2003 GDHS, the neonatal mortality rate has fallen by 33 percent, infant mortality rate by 36 percent, and under-5 mortality rate by 46 percent. During the same time period Ghana has implemented various health policy measures, including the Community-based Health Planning and Services (CHPS) policy, National Health Insurance Policy, which provides for free treatment of children under age 18; free maternal delivery services; and malaria control interventions. The malaria activities include changes in drug policy and national promotion of insecticide treated bednets.

Data from the 2014 GDHS also shows increased antenatal care and postnatal care, improved delivery practices, and improved maternal health (see Chapter 9) attributable to the free maternal delivery policy. Despite these improvements, neonatal mortality has changed only marginally from the 2008 GDHS.

8.3   SOCIOECONOMIC DIFFERENTIALS IN CHILDHOOD MORTALITY

Table 8.2 shows differentials in childhood mortality by socioeconomic variables. To minimise sampling errors associated with mortality estimates and to ensure a sufficient number of cases for statistical reliability, the mortality rates shown in the table are calculated for a 10-year period.

Table 8.2 Early childhood mortality rates by socioeconomic characteristics

Neonatal, postneonatal, infant, child, and under-5 mortality rates for the 10-year period preceding the survey, by background characteristics, Ghana 2014

Background characteristic	Neonatal mortality (NN)	Postneonatal mortality (PNN)[1]	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-5 mortality ($_5q_0$)
Residence					
Urban	33	16	49	16	64
Rural	29	17	46	30	75

Wealth quintile					
Lowest	32	22	55	39	92
Second	26	19	44	30	73
Middle	26	13	39	22	61
Fourth	31	16	47	8	55
Highest	40	11	51	13	64

Note: Figures in parentheses are based on 250-499 unweighted exposed persons.
[1] Computed as the difference between the infant and neonatal mortality rates

Table 8.2 shows that under-5 mortality and child mortality are higher in rural areas than in urban areas: 75 deaths per 1,000 live births in rural areas, which compares with 64 deaths per 1,000 live births in urban areas. Rural-urban differences are marginal in the case of infant and postneonatal mortality rates. Moreover, there are wide differentials in infant and under-5 mortality by region, with under-5 mortality ranging from 47 deaths per 1,000 live births in the Greater Accra region to 111 deaths per 1,000 live births in the Northern region. Under-5 mortality is highest among three regions, Northern (111 deaths per 1,000 live births), Upper West (92 deaths per 1,000 live births), and Ashanti (80 deaths per 1,000 live births). Similarly, infant mortality is highest in Upper West (64 deaths per 1,000 live births), Ashanti (63 deaths per 1,000 live births), and Northern regions (53 deaths per 1,000 live births) and lowest in the Greater Accra region (37 deaths per 1,000 live births) and Brong Ahafo region (38 deaths per 1,000 live births)

As expected, mother's education is inversely related to a child's risk of dying. Under-5 mortality among children born to mothers with no education (92 deaths per 1,000 live births) is substantially higher than that of children born to mothers with middle/JSS/JHS or with a secondary or higher level of education (54-55 deaths per 1,000 live births). Table 8.2 also shows that the risk of dying among children below age 5 tends to decrease with increasing household wealth, from 92 deaths per 1,000 live births in the poorest households to 55 deaths and 64 deaths per 1,000 live births in households in the fourth and highest wealth quintiles , respectively.

8.4 DEMOGRAPHIC DIFFERENTIALS IN MORTALITY

Demographic characteristics of both mother and child play an important role in the survival probability of children. Table 8.3 shows that all childhood mortality is higher among male than female children.

As expected, the relationship between maternal age at birth and childhood mortality is generally U-shaped, being relatively higher among children born to mothers under age 20 and over age 30 than among children born to mothers in the 20-29 age group. This pattern is observed for neonatal, infant, and

under-5 mortality. Neonatal mortality is 42 deaths per 1,000 live births among mothers who are less than 20 years old. This declines to 24 deaths per 1,000 live births among mothers who are age 20–29 and thereafter increases to 38 deaths per 1,000 live births among mothers who are age 30-39. A similar pattern is observed in the infant and under-5 mortality rates. However, postneonatal and child mortality show an inverse relationship. For instance, the postneonatal mortality declined from 20 deaths per 1,000 live births among mothers who are under age 20 to 16 deaths per 1,000 live births among mothers who are age 20-29, and further to 14 deaths per 1,000 live births among mothers who are age 30-39. The U-shape pattern of mortality is again observed for birth order. In general, childhood mortality rates are higher among first-order births and births of seventh or higher order than among births of orders two or three. This is true except for child mortality which is 18 deaths per 1,000 live births among first-order births and it increases to 40 deaths per 1,000 live births among births of seventh or higher order.

Table 8.3 Early childhood mortality rates by demographic characteristics

Neonatal, postneonatal, infant, child, and under-five mortality rates for the 10-year period preceding the survey, by demographic characteristics, Ghana 2014

Demographic characteristic	Neonatal mortality (NN)	Postneonatal mortality (PNN)[1]	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-5 mortality ($_5q_0$)

na = Not available
[1] Computed as the difference between the infant and neonatal mortality rates
[2] Excludes first-order births
[3] Rates for the five-year period before the survey

The spacing of births is another factor that has a significant impact on a child's chances of survival. Generally, shorter birth intervals are associated with higher mortality, both during and after infancy. The 2014 GDHS data confirm this pattern. All childhood mortality rates show a strong relationship with the length of the previous birth interval. For example, infant mortality is more than two times higher among children born less than two years after a preceding sibling than among children born four or more years after a previous child (71 deaths and 33 deaths per 1,000 live births, respectively).

8.5 PERINATAL MORTALITY

The 2014 GDHS asked women to report on any pregnancy loss that occurred in the five years preceding the survey. For each pregnancy that did not end in a live birth, the duration of pregnancy was recorded. In this report, perinatal deaths include pregnancy losses of at least seven months' gestation (stillbirths) and deaths to live births within the first seven days of life (early neonatal deaths). The perinatal mortality rate is the sum of stillbirths and early neonatal deaths divided by the sum of all stillbirths and live births. Information on stillbirths and infant deaths within the first week of life is highly susceptible to

omission and misreporting. Nevertheless, retrospective surveys in developing countries provide more representative and accurate perinatal death rates than do vital registration systems and hospital-based studies.

Table 8.4 shows that out of the 5,776 reported pregnancies of at least seven months' gestation in the five years preceding the survey, 81 were stillbirths and 140 were early neonatal deaths, yielding an overall perinatal mortality rate of 38 per 1,000 pregnancies. Because the rate is subject to a high degree of sampling variation, differences by background characteristics should be interpreted with caution.

Table 8.4 Perinatal mortality

Number of stillbirths and early neonatal deaths, and the perinatal mortality rate for the five-year period preceding the survey, by background characteristics, Ghana 2014

Background characteristic	Number of stillbirths[1]	Number of early neonatal deaths[2]	Perinatal mortality rate[3]	Number of pregnancies of 7+ months duration

Fourth	19	33	47	1,093
Highest	9	26	33	1,057
Total	81	140	38	5,776

Note: Figures in parentheses are based on 250-499 unweighted exposed persons.
[1] Stillbirths are fetal deaths in pregnancies lasting seven or more months.
[2] Early neonatal deaths are deaths at age 0-6 days among live-born children.
[3] The sum of the number of stillbirths and early neonatal deaths, divided by the number of pregnancies of seven or more months' duration, expressed per 1,000.
[4] Categories correspond to birth intervals of <24 months, 24-35 months, 36-47 months, and 48+ months.

The perinatal mortality rate is highest among mothers age 30-39 and among births that occur less than 15 months after the previous birth (47 deaths per 1,000 pregnancies each). It is lowest among births that occur 27 or more months after the previous birth (34 deaths per 1,000 live births). The perinatal mortality rate is marginally higher in urban than in rural areas. It is highest in the Central region and lowest in the Northern region by a difference of as much as 17 deaths per 1,000 pregnancies. By maternal educational and wealth status, perinatal mortality is highest among women with primary education (43 deaths per 1,000 live births) and among births in the fourth quintile households (47 deaths per 1,000 live

births). Perinatal mortality practically has not changed during the past six years (39 deaths per 1,000 pregnancies in the 2008 GDHS and 38 deaths per 1,000 pregnancies in the 2014 GDHS).

8.6 HIGH-RISK FERTILITY BEHAVIOUR

The survival of infants and children depends in part on the demographic and biological characteristics of their mothers. Typically, the probability of dying in infancy is much greater among children born to mothers who are too young (under age 18) or too old (over age 34), children born after a short birth interval (less than 24 months after the preceding birth), and children born to mothers of high parity (more than three children). The risk is elevated when a child is born to a mother who has a combination of these risk characteristics.

Table 8.5 High-risk fertility behaviour

Percent distribution of children born in the five years preceding the survey by category of elevated risk of mortality and the risk ratio, and percent distribution of currently married women by category of risk if they were to conceive a child at the time of the survey, Ghana 2014

| Risk category | Births in the 5 years preceding the survey | | Percentage of currently married women[1] |
	Percentage of births	Risk ratio	
Not in any high risk category	30.8	1.00	18.2[a]
Unavoidable risk category			
First order births between ages 18 and 34 years	20.0	1.00	5.1
Single high-risk category			
Mother's age <18	4.1	1.16	0.1
Mother's age >34	3.1	1.42	7.8
Birth interval <24 months	4.6	1.23	8.9
Birth order >3	18.0	1.31	12.0
Subtotal	29.7	1.29	28.8
Multiple high-risk category			
Age <18 and birth interval <24 months[2]	0.2	*	0.1
Age >34 and birth interval <24 months	0.2	*	0.7
Age >34 and birth order >3	14.3	0.94	33.4
Age >34 and birth interval <24 months and birth order >3	1.4	3.33	5.4
Birth interval <24 months and birth order >3	3.5	1.82	8.3
Subtotal	19.5	1.25	47.9
In any avoidable high-risk category	49.2	1.27	76.7
Total	100.0	na	100.0
Number of births/women	5,695	na	5,321

Note: Risk ratio is the ratio of the proportion dead among births in a specific high-risk category to the proportion dead among births not in any high-risk category. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
na = Not applicable
[1] Women are assigned to risk categories according to the status they would have at the birth of a child if they were to conceive at the time of the survey: current age less than 17 years and 3 months or older than 34 years and 2 months, latest birth less than 15 months ago, or latest birth being of order 3 or higher.
[2] Includes the category age <18 and birth order >3
[a] Includes sterilised women

The first column in Table 8.5 shows the percentages of births occurring in the five years before the survey that fall into the various risk categories. Overall, around 5 in 10 babies are in some avoidable risk category at the time they were born (49 percent). First births to mothers between ages 18 and 34 years, which make up 20 percent of births, are considered an unavoidable risk. Thirty percent of births are in a single high-risk category, and 20 percent are in a multiple high-risk category. The most common avoidable risk factor in a single high-risk category is birth order higher than three (18 percent), while the most common avoidable risk factor in a multiple high-risk category is births to mothers above age 34 and of birth order more than three (14 percent).

The risk ratios in the second column of Table 8.5 denote the relationship between risk factors and mortality. In general, risk ratios are higher for children in a multiple high-risk category than in a single

high-risk category. The most vulnerable births are those to women older than 34, with a birth interval less than 24 months, and a birth order higher than three. This group of children is three times more likely to die as children not in any high-risk category.

The final column of Table 8.5 shows that 77 percent of currently married women have the potential to give birth to a child at an elevated risk of dying. Three in ten women have the potential for a birth in a single high-risk category (mainly too high a birth order, too short a birth interval, and too old a mother). Another five in ten women have the potential to give birth to a child in a multiple high-risk category (mainly, the mother is too old, and the infant is in a birth order too high).

MATERNAL HEALTH

9

Key Findings:

- Ninety-seven percent of women in Ghana receive antenatal care from a skilled provider. This percentage has increased steadily from 82 percent in 1988 to 97 percent in 2014.
- A large proportion of pregnant women in Ghana (87 percent) had four or more antenatal care visits for the most recent live birth, an increase from 78 percent in 2008. The median duration of pregnancy for the first antenatal visit is 3.6 months.
- Seventy-eight percent of mothers with a birth in the five years preceding the survey were protected against neonatal tetanus.
- The percentage of deliveries occurring in a health facility has increased from 42 percent in 1988 to 73 percent in 2014; the percentage of births attended by a skilled provider has increased from 40 percent to 74 percent over the same period.
- About 8 in 10 mothers (81 percent) receive a postnatal checkup within the critical first two days after delivery.

The health care that a mother receives during pregnancy, at the time of delivery, and soon after delivery is important for the survival and well-being of both the mother and her child. This chapter presents findings on several topics related to maternal health—antenatal, delivery, and postnatal care—as well as problems in accessing care. These findings are important for designing appropriate strategies and interventions to improve maternal and newborn health care services.

9.1 ANTENATAL CARE

9.1.1 Antenatal Care Coverage

The major objective of antenatal care (ANC) is to identify and treat problems such as anaemia and infections during pregnancy. It is during an antenatal care visit that screening for complications and advice on a range of issues, including birth preparedness, place of delivery, and referral of mothers with complications, occurs. Information on antenatal care is of great value in identifying subgroups of women who do not use such services and is useful in planning improvements in these services. The 2014 Ghana Demographic and Health Survey (GDHS) findings on ANC provide information on the type of service provider, the number of antenatal care visits, the stage of pregnancy at the time of the first visit, and the services and information provided during antenatal care, including whether tetanus toxoid injections were received.

Table 9.1 presents the percent distribution of women age 15-49 who had a live birth in the five years preceding the survey. They are shown by the type of antenatal care provider consulted during the pregnancy for the most recent birth, according to background characteristics. If a woman received antenatal care from more than one provider, the provider with the highest qualifications was recorded.

Survey results show that more than 9 in 10 mothers (97 percent) receive antenatal care from a skilled provider: 22 percent from a doctor, 69 percent from a nurse/midwife, and 7 percent from a community health officer/nurse. Almost no mothers receive antenatal care from a traditional birth attendant. Overall, only 3 percent of mothers receive no antenatal care for their most recent birth in the five years before the survey.

Differences in antenatal care coverage by various background characteristics are not pronounced, except for some slight variations by birth order and region. Mothers are somewhat more likely to receive ANC from a skilled professional for first-order births (99 percent) than for births of sixth or higher order (94 percent). It is notable that less than 10 percent of mothers in the three Northern regions (Northern, Upper East, and Upper West) receive ANC from a doctor (3 percent, 6 percent, and 7 percent, respectively).

Table 9.1 Antenatal care

Percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by antenatal care (ANC) provider during pregnancy for the most recent birth and the percentage receiving antenatal care from a skilled provider for the most recent birth, according to background characteristics, Ghana 2014

Note: If more than one source of ANC is mentioned, only the provider with the highest qualifications is considered in this tabulation.
[1] Skilled provider includes doctor, nurse/midwife, and community health officer/nurse.

9.1.2 Number and Timing of Antenatal Care Visits

Antenatal care is more beneficial in preventing adverse outcomes when it is sought early in the pregnancy and is continued until delivery. Under normal circumstances, the World Health Organization (WHO) recommends that a woman without complications make at least four antenatal care visits, the first of which should take place during the first trimester. Table 9.2 presents information on antenatal care visits, including the number of visits and the timing of the first visit.

A large proportion of pregnant women in Ghana (87 percent) had four or more antenatal care visits for the most recent live birth, 92 percent in urban areas and 83 percent in rural areas. This is an increase from 78 percent of pregnant women as reported in the 2008 GDHS.

Table 9.2 Number of antenatal care visits and timing of first visit

Percent distribution of women age 15-49 who had a live birth in the five years preceding the survey by number of antenatal care (ANC) visits for the most recent live birth, and by the timing of the first visit, and among women with ANC, median months pregnant at first visit, according to residence, Ghana 2014

	Residence		
Number and timing of ANC visits	Urban	Rural	Total
Number of ANC visits			
None	1.3	3.6	2.6
1	0.6	1.5	1.1
2-3	5.4	11.3	8.6
4+	92.3	82.9	87.3
Don't know/missing	0.4	0.7	0.5
Total	100.0	100.0	100.0
Number of months pregnant at time of first ANC visit			
No antenatal care	1.3	3.6	2.6
<4	67.8	60.7	64.0
4-5	25.3	28.9	27.2
6-7	5.2	6.1	5.7
8+	0.3	0.6	0.5
Total	100.0	100.0	100.0
Number of women	1,914	2,228	4,142
Median months pregnant at first visit (for those with ANC)	3.5	3.6	3.6
Number of women with ANC	1,888	2,148	4,036

Data further show that more than 6 in 10 pregnant women (64 percent) made their first antenatal care visit before the fourth month of pregnancy, as recommended, compared with 55 percent in 2008. This percentage is higher in urban than in rural areas (68 percent versus 61 percent). An additional 27 percent of women had their first ANC visit between the fourth and fifth month of pregnancy.

The median duration of pregnancy at the first antenatal care visit is 3.6 months (3.5 months in urban areas and 3.6 months in rural areas).

9.1.3 Components of Antenatal Care

The quality of antenatal care is measured to a large extent by the essential service package provided to pregnant women. The components of this package include prevention and management of anaemia and malaria, which are achieved through screening and appropriate management. Micronutrient supplementation, tetanus immunisation, and monitoring of certain vital signs to help in the early detection and management of complications that may arise are also included in this important care package. Pregnancy complications are a primary source of maternal and newborn morbidity and mortality. Therefore, ensuring that pregnant women receive information on the signs of complications is an important component of good antenatal care.

To help assess antenatal care services, respondents were asked whether they had been advised of possible pregnancy complications and whether they had received certain screening tests during at least one of their antenatal care visits. Caution should be taken in the interpretation of this information on the components of antenatal care because it is dependent on pregnant women's recall of events during antenatal care that may have taken place a number of years before the interview. Nevertheless, the results are useful in providing insights into the content of antenatal care.

Table 9.3 presents information on the percentage of pregnant women who took iron tablets or syrup, those who were informed of the signs of pregnancy complications, and who received selected

services during antenatal care visits for their most recent birth in the five years preceding the survey. Information on pregnant women who took malaria preventive treatment is covered in Chapter 12 of this report.

Table 9.3 Components of antenatal care

Among women age 15-49 with a live birth in the five years preceding the survey, the percentage who took iron tablets or syrup and medicines for intestinal parasites during the pregnancy of the most recent birth, and among women receiving antenatal care (ANC) for the most recent live birth in the five years preceding the survey, the percentage receiving specific antenatal services, according to background characteristics, Ghana 2014

Background characteristic	Among women with a live birth in the past five years, the percentage who during the pregnancy of their last birth:		Number of women with a live birth in the past five years	Among women who received antenatal care for their most recent birth in the past five years, the percentage with selected services:				Number of women with ANC for their most recent birth

Total	91.9	39.4	4,142	83.9	98.8	97.3	98.1	4,036

The vast majority of women (92 percent) took iron supplements during their most recent pregnancy in the last five years. Variations by various background characteristics are minimal. Women are somewhat less likely to take iron supplements for births of sixth or higher order (88 percent), if they reside in the Volta, Eastern, and Northern regions (89 percent each), if they have no education, and if they belong to the lowest wealth quintile (89 percent each).

Only about 4 in 10 pregnant women (39 percent) took intestinal parasite medicines; the low proportion could be attributed to fear of side effects from intestinal parasite medicines among pregnant women, particularly in early pregnancy. In Ghana, intestinal parasite medicines are prescribed by health professionals either based on laboratory test results or the extent of parasite presence in a given locality. The percentage of women who receive intestinal parasite medicines tends to increase with increasing birth order; this percentage is higher among women in rural than in urban areas (42 percent versus 36 percent). Women in Upper East are the most likely to receive intestinal parasite medicines (70 percent) and women

in Ashanti are the least likely to do so (25 percent). This proportion is lowest among women with a secondary or higher education (34 percent), and among those in the highest wealth quintile (29 percent).

Table 9.3 shows that the proportion of women who undergo basic tests during pregnancy is nearly universal in Ghana. More than 9 in 10 women with a live birth in the five years preceding the survey had their blood pressure measured (99 percent), had a blood sample taken (98 percent), and had their urine sampled (97 percent) during ANC for their most recent pregnancy. There are no major variations in these components of antenatal care by background characteristics.

More than 8 in 10 (84 percent) of women with a live birth in the last five years were informed of the signs of pregnancy complications. The likelihood of receiving the information about the signs of pregnancy complications is lowest among youngest mothers under age 20 (77 percent). This percentage is lower among women in rural than in urban areas (87 percent versus 81 percent). Regional differences are substantial; 95 percent of women in Greater Accra are informed of signs of pregnancy complications compared with slightly more than half (54 percent) of women in Upper West. This percentage is highest among women with a secondary or higher education (87 percent) and those in the wealthiest households (92 percent).

9.1.4 Tetanus Immunisation

Neonatal tetanus is one of the leading causes of neonatal deaths in developing countries where a high proportion of deliveries are conducted at home or in places where hygienic conditions may be poor. Tetanus toxoid (TT) immunisation is given to pregnant women to prevent neonatal tetanus. If a woman has received no previous TT injections, for full protection a pregnant woman needs two doses of TT during pregnancy. However, if a woman was immunised before she became pregnant, she may require one or no TT injections during pregnancy, depending on the number of injections she has ever received and the timing of the last injection. For a woman to have lifetime protection, a total of five doses is required.

Table 9.4 shows the percentage of women 15-49 who had a live birth in the five years preceding the survey and whose last birth was protected against neonatal tetanus. Births of about 8 in 10 mothers (78 percent) were protected against neonatal tetanus; about 6 in 10 pregnant women (57 percent) received two or more tetanus injections during their last pregnancy.

The percentage of mothers who received two or more doses of tetanus injections for their last pregnancy decreases with women's age at birth and tends to

Table 9.4 Tetanus toxoid injections

Among mothers age 15-49 with a live birth in the five years preceding the survey, the percentage receiving two or more tetanus toxoid injections during the pregnancy for the last live birth and the percentage whose last live birth was protected against neonatal tetanus, according to background characteristics, Ghana 2014

Background characteristic	Percentage receiving two or more injections during last pregnancy	Percentage whose last birth was protected against neonatal tetanus[1]	Number of mothers

[1] Includes mothers with two injections during the pregnancy of her last birth, or two or more injections (the last within 3 years of the last live birth), or three or more injections (the last within 5 years of the last live birth), or four or more injections (the last within 10 years of the last live birth), or five or more injections at any time prior to the last birth.

decrease with increasing birth order. There are variations by urban-rural residence and by region. Sixty percent of mothers in urban areas received two or more TT injections during their last pregnancy compared with 55 percent in rural areas. TT coverage with two or more doses ranges from 43 percent of births in the Upper West region to 69 percent in the Central region. Education and wealth have a positive impact on receipt of tetanus toxoid injections, with coverage of two or more doses ranging from a low of 51 percent among mothers with no education or with primary education to a high of 67 percent among mothers with a secondary or higher education. Similarly, TT coverage with two or more doses ranges from 47 percent among mothers in the poorest households to 67 percent among those in the wealthiest households.

Between 2008 and 2014, the percentage of mothers who received at least two TT injections for their last birth increased slightly from 56 percent to 57 percent, and the percentage whose last birth was protected against neonatal tetanus increased moderately from 72 percent to 78 percent.

9.2 DELIVERY CARE

Labour and delivery is the shortest and most critical period of the pregnancy-childbirth continuum because most maternal deaths arise from complications during delivery. Even with the best possible antenatal care, any delivery can become a complicated one and, therefore, skilled assistance is essential to safe delivery care. For numerous reasons many women do not seek skilled care even when they understand the safety reasons for doing so. Some reasons include cost of the service, distance to the health facility, and concerns about the quality of care. The availability of free maternity services and community-based health planning services (CHPS) has helped remove barriers to accessing skilled maternity care. The CHPS compounds are manned by community health officers or nurses, some of whom are midwives or have midwifery skills. They attend deliveries and make referrals if complications arise.

9.2.1 Place of Delivery

In the 2014 GDHS eligible women were asked to report the place of birth for each child born in the five years preceding the survey. Table 9.5 shows the percent distribution of live births in the five years preceding the survey by place of delivery, according to background characteristics. Overall, 73 percent of births were delivered in health facilities, with the public sector accounting for the largest proportion (65 percent).

Delivery in a health facility decreases with increasing birth order, from 84 percent among first-order births to 54 percent among births of sixth or higher order. As expected, the proportion of births delivered in a health facility increases substantially with increasing number of ANC visits. Births in urban areas are much more likely to be delivered in an institutional setting than births in rural areas (90 percent versus 59 percent). Delivery in a health facility varies widely by region from 63 percent of births in Upper West to 93 percent of those in Greater Accra. There is a strong association between health facility deliveries and mother's education and wealth quintile. The proportion of deliveries occurring in a health facility increases from 52 percent for births to women with no education to 95 percent for births to women with a secondary or higher education. Similarly, health facility deliveries are substantially fewer among births in the poorest households (46 percent) than those in the wealthiest households (96 percent).

9.2.2 Assistance at Delivery

Obstetric care from a health professional during delivery is recognised as critical for the reduction of maternal and neonatal mortality. Children delivered at home are usually more likely to be delivered without assistance from a trained provider, whereas children delivered at a health facility are more likely to be delivered by a trained health professional.

Table 9.6 shows delivery assistance for all live births in the preceding five years, by type of provider, according to background characteristics. Three-quarters of births in Ghana (74 percent) are delivered with the assistance of a skilled health professional: 14 percent are assisted by a doctor, 57 percent by a nurse/midwife, and 3 percent by a community health officer/nurse. Data further show that 16 percent of births are delivered by a traditional birth attendant, 7 percent are assisted by a relative or other person, and 3 percent of deliveries are not assisted by anyone. It is notable that, even though nationally, only 3 percent of births are assisted by a community officer/nurse, this is true for almost one in five births (18 percent) in Upper West, indicating the crucial role of these providers in this region. Furthermore, data show that traditional birth attendants play an important role in the Northern region, assisting in the delivery of 4 in 10 births (41 percent).

Delivery assistance by a skilled health professional shows little association with women's age. However, it decreases steadily with increasing birth order from 85 percent of first-order births to 55 percent of births of sixth or higher order. This proportion increases substantially with the number of ANC visits, and it is higher among births in urban than in rural areas (90 percent versus 60 percent). Skilled provider assistance at delivery increases notably with mother's level of education and wealth quintile. For example, 52 percent of births to women with no education are assisted by a skilled health professional, as compared with 96 percent of births to women with a secondary or higher education. This percentage ranges from 47 percent of births in the poorest households to 97 percent of those in the richest households.

Table 9.6 Assistance during delivery

Percent distribution of live births in the five years preceding the survey by person providing assistance during delivery, percentage of birth assisted by a skilled provider, and the percentage delivered by caesarean-section, according to background characteristics, Ghana 2014

Note: If the respondent mentioned more than one person attending during delivery, only the most qualified person is considered in this tabulation. Totals may not add up to 100 percent because women with missing information have been deleted. Total includes 22 women for whom information on ANC visits is missing and 2 women for whom information on place of delivery is missing.
[1] Skilled provider includes doctor, nurse/midwife, and community health officer/nurse.
[2] ANC visits includes only the most recent birth in the five years preceding the survey.

Table 9.6 also presents data on the prevalence of deliveries by caesarean section (C-section). Nationally, 13 percent of births are delivered by cesarean section, an increase from 7 percent in 2008. Delivery by C-section is highest among births to women age 35-49 (17 percent), first-order births (18

percent), births for whom mothers had four or more ANC visits (15 percent), births in urban areas (19 percent) and in the Greater Accra region (23 percent), births to mothers with a secondary or higher education (27 percent), and those in the richest households (28 percent).

Figure 9.1 shows the percent distribution of mothers with a birth in the five years preceding the survey who delivered their last birth in a health facility, by duration of stay in the health facility and type of delivery. As expected, the large majority of women with a vaginal birth stayed at a health facility for two days or fewer (88 percent). In contrast, the large majority of women who delivered by C-section (89 percent) stayed at a health facility for three or more days.

GDHS 2014

9.3   TRENDS IN MATERNAL CARE

Figure 9.2 shows trends in maternal care across the six GDHS surveys conducted in Ghana. All the maternal care indicators improved over the past two and a half decades. The percentage of women receiving antenatal care from a skilled provider has increased steadily from 82 percent in 1988 to 97 percent in 2014; the percentage of deliveries occurring in a health facility has increased from 42 percent in 1988 to 73 percent in 2014, and the percentage of births attended by a skilled provider has increased from 40 percent in 1988 to 74 percent in 2014.

Figure 9.2 Trends in maternal health care, 1988-2014

Percent
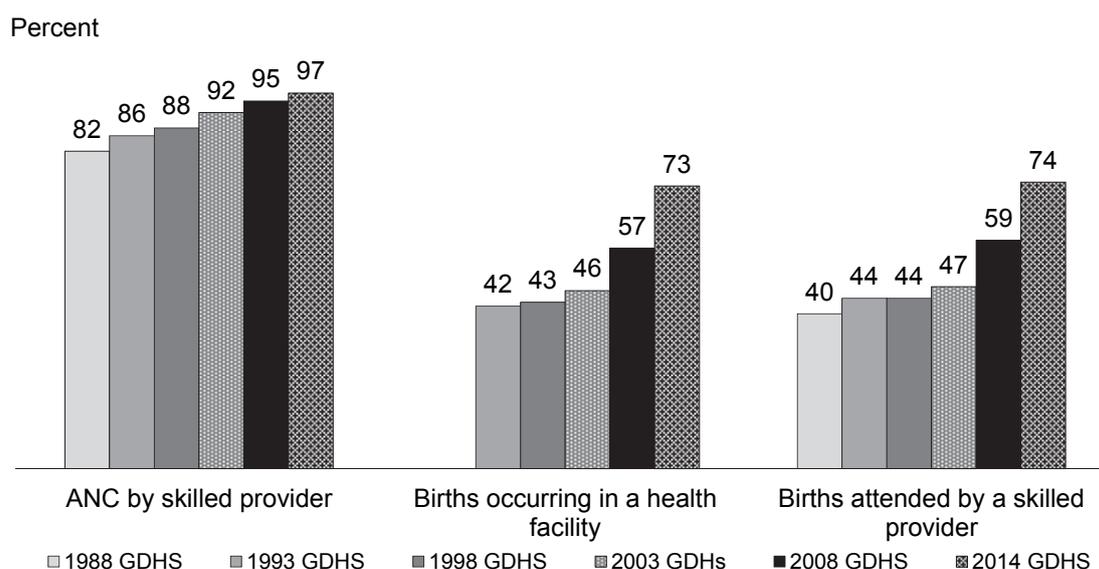

Note: Data for the 1988, 1993, and 1998 surveys refer to births, whereas data for antenatal care for the 2003, 2008, and 2014 surveys refer to women who had a live birth. The reference period is five years preceding the survey except for 1993, which refers to the three years preceding the survey. In the 2008 and 2014 surveys, a skilled provider includes a community health officer, while in all previous surveys a community health officer was not included. For the 1988 survey, data for births that occurred in a health facility are missing.

9.4 POSTNATAL CARE FOR THE MOTHER

A large proportion of maternal and neonatal deaths occur during the first 48 hours after delivery. Thus, prompt postnatal care for both the mother and the child is important to cater for any complications arising from the delivery, as well as to provide the mother with important information on how to care for herself and her child. Safe motherhood programmes recommend that all women receive a check of their health within two days after delivery. Women who deliver at home should go to a health facility for postnatal care services within 24 hours, and subsequent visits (including those by women who deliver in a health facility) should be made at three days, seven days, and six weeks after delivery. It is also recommended that women who deliver in a health facility should be kept there for at least 48 hours (up to 72 hours depending on the capacity of the institution), so that the mothers and infants may be monitored by skilled personnel.

To assess the extent of postnatal care utilization, respondents were asked, for the last birth in the two years preceding the survey, whether they had received a checkup after delivery, the timing of the first checkup, and the type of health provider performing the postnatal checkup. This information is presented according to background characteristics in Tables 9.7 and 9.8

9.4.1 Timing of First Postnatal Checkup for the Mother

Table 9.7 shows that about 7 in 10 women (72 percent) receive a postnatal checkup within 24 hours of delivery, and about 8 in 10 (81 percent) are checked within the critical first two days. Four percent of women receive postnatal care 3-41 days after delivery.

Having a postnatal checkup within the most crucial period (first two days) is inversely associated with the number of children a woman has; women with births of sixth or higher order are least likely to receive an early postnatal checkup (67 percent). Women delivering in a health facility are more than twice as likely to have a postnatal checkup within the first two days as women delivering elsewhere (93 percent and 45 percent, respectively). Women living in rural areas (74 percent), those living in the Northern region (59 percent), women with no education (68 percent), and those in the poorest households (65 percent) are the least likely to have an early postnatal checkup compared with other subgroups.

Table 9.7 Timing of first postnatal checkup for the mother

Among women age 15-49 giving birth in the two years preceding the survey, the percent distribution of the mother's first postnatal checkup for the last live birth by time after delivery, and the percentage of women with a live birth in the two years preceding the survey who received a postnatal checkup in the first two days after giving birth, according to background characteristics, Ghana 2014

| Background characteristic | Time after delivery of mother's first postnatal checkup | | | | | | No postnatal checkup[1] | Total | Percentage of women with a postnatal checkup in the first two days after birth | Number of women |

[1] Includes women who received a checkup after 41 days

9.4.2 Type of Provider of First Postnatal Checkup for the Mother

The skill level of the provider who performs the first postnatal checkup also has important implications for maternal and neonatal health. Table 9.8 shows that 45 percent of women received postnatal care from a nurse/midwife, 24 percent from a doctor, 4 percent from a community health officer/nurse, and 8 percent from a traditional birth attendant. Mothers of first-order births, those who delivered in a health facility, mothers living in urban areas and in the Greater Accra region, those with a secondary or higher education, and mothers from the wealthiest households are more likely to have received postnatal care from a skilled health provider than other mothers.

Table 9.8 Type of provider of first postnatal checkup for the mother

Among women age 15-49 giving birth in the two years preceding the survey, the percent distribution by type of provider of the mother's first postnatal health check in the two days after the last live birth, according to background characteristics, Ghana 2014

Note: Total includes 1 woman for whom information on place of delivery is missing.

9.5 POSTNATAL CARE FOR THE NEWBORN

As mentioned, a significant proportion of neonatal deaths occur during the first few hours of life (48 hours) after delivery. The provision of postnatal care services for newborns should therefore start as soon as possible after the child is born. The timing of the postnatal checkup for the newborn is similar to that of the mother in that it should occur within two days after birth.

Table 9.9 shows that 30 percent of last births in the two years preceding the survey received a postnatal checkup; 1 percent of the newborns received a postnatal checkup less than 1 hour after birth, 12 percent within 1 to 3 hours, 5 percent within 4 to 23 hours, 5 percent within 1-2 days, and 7 percent within 3-6 days. Overall, 23 percent of births received a checkup in the first two days after birth.

A large majority of newborns (70 percent) did not receive any postnatal checkup.

Birth order, place of delivery, residence, mother's education level, and wealth quintile are closely linked to the timing of the first postnatal checkup for the newborn. First-order newborns and those whose mothers deliver in a health facility (25 percent each), newborns in Upper East (60 percent), newborns of

mothers with primary or a secondary or higher education (27 percent each), and those from the richest households (29 percent) have a greater chance of receiving a postnatal checkup within two days after birth compared with other newborns.

Percent distribution of last births in the two years preceding the survey by time after birth of first postnatal checkup, and the percentage of births with a postnatal checkup in the first two days after birth, according to background characteristics, Ghana 2014

[1] Includes newborns who received a checkup after the first week

9.5.1 Type of Provider of First Postnatal Checkup for the Newborn

Table 9.10 shows the type of provider of the newborn's first postnatal checkup that took place within two days after birth. Overall, 20 percent of newborns received a postnatal checkup from a skilled provider: 19 percent from a doctor, 2 percent from a nurse/midwife, and a very small percentage (less than 1 percent) from a community health officer/nurse. Two percent of newborns received a postnatal checkup from a traditional birth attendant.

Seventy-seven percent of newborns did not receive a postnatal checkup within the first two days after birth. Differentials by background characteristics are similar to those observed for last births in the two years preceding the survey by time of the newborn's first postnatal checkup (Table 9.9).

Table 9.10 Type of provider of first postnatal checkup for the newborn

9.6 PROBLEMS IN ACCESSING HEALTH CARE

Many factors can prevent women from getting medical advice or treatment for themselves when they are sick. Information on such factors is particularly important in understanding and addressing the barriers women may face in seeking care during pregnancy and at the time of delivery.

In the 2014 GDHS, women were asked whether or not each of the following factors would be a significant problem for them in seeking medical care: getting permission to go for treatment, getting money for treatment, distance to a health facility, and not wanting to go alone. Table 9.11 shows that more than half of women (51 percent) reported that at least one of these problems would pose a barrier to seeking health care for themselves when they are sick. More than 4 in 10 women (42 percent) stated that getting money for treatment is a serious problem in accessing health care for themselves, one in four (25 percent) stated distance to a health facility as a serious problem, and about one in six (16 percent) stated that not wanting to go alone is a problem. Only 6 percent of women perceived getting permission to go for treatment as a serious problem.

Women with five or more children (62 percent), those who are divorced, separated, or widowed (57 percent), unemployed women or those who are employed but not for cash (54 percent), women living in rural areas (58 percent), and those residing in the Northern region (71 percent) are more likely than other women to cite having at least one of these problems in seeking health care for themselves. This percentage is also highest among women with no education and women in the poorest households (64 percent and 68 percent, respectively).

Table 9.11 Problems in accessing health care

Percentage of women age 15-49 who reported that they have serious problems in accessing health care for themselves when they are sick, by type of problem, according to background characteristics, Ghana 2014

CHILD HEALTH AND EARLY DEVELOPMENT

10

Key Findings:

- Ten percent of newborns have low birth weights (less than 2.5 kg).
- The proportion of children age 12-23 months who have received all basic immunisations has dropped from 79 percent in 2008 to 77 percent in 2014.
- Four percent of children under age 5 showed symptoms of acute respiratory infection in the two weeks before the survey; and about one half of these newborns were taken to a health facility or provider for advice or treatment.
- About half of children age 4-15 were engaged by an adult household member in more than four activities that support learning during the seven days preceding the survey; children living in the richest households were almost as likely as those living in the poorest households to engage in these activities.
- Over half of children age 4-15 have not had anyone read to them, and over one-fifth live in households with no children's books or reading materials.
- More than one-third of the children who attended school in the 2014-2015 school year regularly brought their reading materials home.
- Nearly 6 in 10 household respondents want children age 4-15 to be taught in both English and a local language while, about 3 in 10 prefer their children to be taught in English only.
- The majority of children age 4-15 years who attended school in the 2014-2015 school year walked to school (82 percent) and one-third spend more than 20 minutes to get to school.

This chapter presents findings from the 2014 GDHS on child health and early development. The first part of the chapter discusses data on child health, including neonatal conditions (weight and size at birth), vaccination status, and treatment practices the three major childhood illnesses of acute respiratory infection (ARI), fever, and diarrhoea. The information on weight and size, treatment practices, and contact with health facilities during illness paves the way for strategic planning and implementation of programmes to reduce neonatal and infant mortality. When combined with information on childhood mortality, this information can be used to identify those women and children who face increased risk because they do not fully use existing maternal and child health (MCH) services, and to assist with planning improvements for these services.

Information was obtained for all live births that occurred in the five years preceding the survey. Wherever possible, data from the 2014 GDHS are compared with data from the five earlier DHS surveys in Ghana, conducted in 1988, 1993, 1998, 2003, and 2008. However, analysis of trends in maternity care indicators is complicated by differences among the questions asked. The first three GDHS surveys asked questions on antenatal care and tetanus injections for all births, whereas the 2003, 2008, and 2014 surveys confined these questions to the most recent birth. In addition, the questions on maternity care and children's health referred to periods of varying lengths of time (sometimes five years and sometimes three years) preceding the survey. Although it is possible to adjust for some of these inconsistencies, it is not possible to do so for all. Therefore, caution should be used when interpreting the trend data.

The second part of the chapter focuses on early childhood development. It presents information on how parents and household members engage and support children's learning and development, as well as the mode of travel and time it takes to get to school.

10.1　Child's Size and Weight at Birth

A child's birth weight or size at birth indicates the child's vulnerability to the risk of childhood illness and the child's chance of survival. Children whose birth weight is less than 2.5 kilograms, or children reported to be *very small* or *smaller than average* are considered to have a higher than average risk of early childhood death. For births in the five years preceding the survey, birth weight was recorded on the questionnaire if available from written records or mother's recall. Because birth weight may not be known for many babies, the mother's estimate of the baby's size at birth was also obtained. Even though the estimate is subjective, it can be a useful proxy for the weight of the child.

Table 10.1 presents information on child's weight and size at birth, according to background characteristics. Sixty percent of children born in the five years preceding the survey were weighed at birth. Among children with a reported birth weight, 10 percent were of low birth weight (less than 2.5 kg). The results on size of the baby at birth show only small differences by background characteristics. The proportion of babies reported to be of low birth weight was highest in teenage mothers (12 percent) and among first-order births (12 percent). The Eastern region has the highest proportion of babies with low birth weight (14 percent), while the Volta region has the lowest proportion (6 percent). Women in the lowest wealth quintile recorded the highest proportion of babies with low birth weight (11 percent).

Overall, sixteen percent of births are reported to be very small or smaller than average.

Table 10.1 Child's size and weight at birth

Percent distribution of live births in the five years preceding the survey by mother's estimate of baby's size at birth, percentage of live births in the five years preceding the survey that have a reported birth weight, and among live births in the five years preceding the survey with a reported birth weight, percentage less than 2.5 kg, according to background characteristics, Ghana 2014

| Background characteristic | Percent distribution of all live births by size of child at birth | | | | | Percentage of all births that have a reported birth weight[1] | Number of births | Births with a reported birth weight[1] | |

[1] Based on either a written record or the mother's recall

10.2 VACCINATION COVERAGE

The 2014 GDHS collected information on immunisation coverage for all children born in the five years before the survey. The government of Ghana has adopted the World Health Organisation (WHO) and UNICEF guidelines for vaccinating children. According to these guidelines, to be considered fully vaccinated, a child should receive the following vaccinations: one dose each of BCG and measles, three doses of polio vaccine, and three doses of DPT. In addition, in Ghana, a vaccine against yellow fever is recommended for children. BCG, which protects against tuberculosis, should be given at birth or at first clinical contact. DPT protects against diphtheria, pertussis (whooping cough), and tetanus. A dose of polio vaccine is given at birth (Polio 0) or within 13 days of birth. DPT and polio vaccine guidelines require three vaccinations at approximately 6, 10, and 14 weeks of age. The measles and yellow fever vaccines are given at nine months. Currently, the pentavalent vaccine, (DPT-HepB-Hib) introduced in 2002, has replaced the DPT vaccine. This vaccine contains, in addition to DPT, the hepatitis B vaccine and a vaccine

against *Haemophilus influenza* type B. It is recommended that children receive the complete schedule of vaccinations before 12 months.

In 2012, the Ministry of Health introduced two new vaccines, the pneumococcal and rotavirus vaccines. These protect children from pneumococcal diseases (particularly pneumonia and other invasive pneumococcal diseases) and diarrhea, respectively. The country had earlier in the year introduced a measles second-dose vaccine at 18 months. In 2013, the Ministry of Health replaced the measles-only vaccine at nine months with a rubella-containing measles vaccine [Measles-Rubella (MR) vaccine] also given at nine months. Ghana follows a schedule for the administration of all basic childhood vaccines. BCG is given shortly after birth. Oral polio vaccine is given at birth and at approximately age 6, 10, and 14 weeks. Pentavalent vaccine is also given at approximately age 6, 10, and 14 weeks. Measles-rubella and yellow fever vaccines are given at or soon after the child reaches 9 calendar months (39 weeks). The rotavirus vaccine is given at age 6 and 10 weeks. The pneumococcal vaccine is administered as an injection to infants in three doses at age 6, 10, and 14 weeks. The measles-only dose offered to children at 18 months is primarily a booster dose. It is recommended that all vaccinations be recorded on a card that is given to the parents or guardians.

In the 2014 GDHS, information on vaccination coverage was obtained in two ways—from health cards and from mother's verbal reports. All mothers were asked to show the interviewer the health card on which the child's immunisations are recorded. If the card was available, the interviewer copied the dates of each vaccination received. If a vaccination was not recorded on the card, the mother was asked to recall whether that particular vaccination had been given. If the mother was not able to present a card for a child, she was asked to recall whether the child had received BCG, polio, pentavalent, pneumococcal, rotavirus, measles, and yellow fever vaccines. If she recalled that the child had received the polio, pentavalent, measles, pneumococcal or rotavirus vaccines, she was asked about the number of doses that the child received.

The data presented in Table 10.2.1 are for children age 12-23 months, the youngest cohort of children who have reached the age by which they should have had the basic vaccines, and are restricted to children who were alive at the time of the survey. The table shows the percentage of children age 12-23 months who received specific vaccines at any time before the survey by source of information. Overall, 77 percent of children age 12-23 months are fully immunised (have received all basic vaccinations). This percentage is slightly lower than that reported in the 2008 GDHS (79 percent). Only 2 percent of children in Ghana have not received any vaccinations; in the 2008 GDHS, by comparison, 1 percent of children was reported to have not received any vaccinations. Seventy-one percent of children age 12-23 months were fully immunised by age 12 months, which is slightly higher than that reported in the 2008 GDHS (70 percent).

With respect to specific vaccines, 97 percent of children have received BCG, 97 percent have received the first dose of pentavalent vaccine, 97 percent have received polio 1, 93 percent have received the first dose of pneumococcal vaccine, and 91 percent have received one dose of rotavirus vaccine. Coverage for the pentavalent, polio, pneumococcal, and rotavirus vaccinations declines with subsequent doses; 89 percent of children received the recommended three doses of pentavalent (DPT-HepB-Hib), 84 percent received three doses of polio, 89 percent received two doses of rotavirus, and 84 percent received three doses of pneumococcal vaccine. Coverage of the first dose of measles vaccine is 89 percent and that of yellow fever is 88 percent, similar to that reported in the 2008 GDHS (90 percent and 89 percent, respectively, for measles and yellow fever).

Table 10.2.1 Vaccinations by source of information: Children age 12-23 months

Percentage of children age 12-23 months who received specific vaccines at any time before the survey, by source of information (vaccination card or mother's report), and percentage vaccinated by 12 months of age, Ghana 2014

Source of information	BCG	Pentavalent			Polio[1]				Measles 1	Pneumococcal			Rotavirus		Yellow fever	All age appropriate vaccinations[2]	All basic vaccinations[3]	No vaccinations	Number of children

Vaccinated by 12 months of age[4]	96.6	96.5	95.3	87.7	78.8	97.0	93.4	83.3	82.5	93.2	91.0	83.0	90.8	88.5	79.1	50.8	71.1	1.6	1,113

[1] Polio 0 is the polio vaccination given at birth.
[2] BCG, three doses of pentavalent (DPT-HepB-Hib) vaccine, four doses of polio vaccine, one dose of measles, three doses of pneumococcal vaccine, two doses of rotavirus vaccine, and one dose of yellow fever
[3] BCG, measles, and three doses each of pentavalent (DPT-HepB-Hib) and polio vaccine (excluding polio vaccine given at birth)
[4] For children whose information is based on the mother's report, the proportion of vaccinations given during the first year of life is assumed to be the same as for children with a written record of vaccination.

Table 10.2.2 shows the percentage of children age 24-35 months who received specific vaccines at any time before the survey by source of information and proportion vaccinated by the appropriate age. Overall, 36 percent of children age 24-35 months have received all age-appropriate vaccinations. Sixty-four percent of children age 24-35 months received all age appropriate vaccinations by the recommended age. With respect to specific vaccines by the appropriate age, 97 percent of children received BCG, 96 percent received the first dose of pentavalent vaccine, 96 percent received polio 1, 75 percent received the first dose of pneumococcal vaccine, and 71 percent received the first dose of rotavirus vaccine. As expected, vaccination coverage by the recommended age for the pentavalent, polio, pneumococcal, and rotavirus vaccinations declines with subsequent doses; 86 percent of children received the recommended three doses of pentavalent (DPT-HepB-Hib), 80 percent received three doses of polio, 61 percent received three doses of pneumococcal vaccine, and 66 percent received two doses of rotavirus vaccine. Coverage of the first dose vaccines by the recommended age is 90 percent for measles vaccine, 87 percent for yellow fever, and 60 percent for the second dose of measles. The results of the 2014 GDHS relate to fieldwork that took place from September to December, 2014. Therefore, the relatively lower coverage for the newer vaccines (rotavirus and pneumococcal) in children age 24-35 months is probably the result of missed opportunities for children who were, at the time of the introduction, relatively older, and had taken more than their first doses of the traditional vaccines given at 6, 10, and 14 weeks. Consequently, the results should be interpreted with caution.

Table 10.2.2 Vaccinations by source of information: Children 24-35 months

Percentage of children age 24-35 months who received specific vaccines at any time before the survey, by source of information (vaccination card or mother's report), and percentage vaccinated by appropriate age, Ghana 2014

[1] Polio 0 is the polio vaccination given at birth.
[2] BCG, three doses of pentavalent (DPT-HepB-Hib) vaccine, four doses of polio vaccine, two doses of measles, three doses of pneumococcal vaccine, two doses of rotavirus vaccine, and one dose of yellow fever
[3] For children whose information is based on the mother's report, the proportion of vaccinations given during the first year of life is assumed to be the same as for children with a written record of vaccination.
[4] By 12 months of age for all vaccines, except measles 2 vaccine, which should be received by 24 months of age

Table 10.3.1 shows the percentage of children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), and the percentage with a vaccination card by background characteristics. Vaccination coverage does not differ substantially by background characteristics, but there are some notable trends. Children in urban areas are most likely to have all basic vaccinations, but children in rural areas are most likely to have all age appropriate vaccinations. Children who are their mother's sixth or higher birth have lower rates of age-appropriate vaccination and, in fact, are more likely to have never been vaccinated. Children whose mothers have a secondary or higher education have noticeably higher rates of both basic and age-appropriate vaccinations. The proportion of children with all basic vaccinations does not vary with the mother's wealth quintile, but age appropriate vaccinations increase with increasing wealth of the mother.

Table 10.3.1 Vaccinations by background characteristics: Children 12-23 months

Percentage of children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), the percentage ever with a vaccination card, and the percentage with a vaccination card seen, by background characteristics, Ghana 2014

[1] Polio 0 is the polio vaccination given at birth.
[2] BCG, three doses of pentavalent (DPT-HepB-Hib) vaccine, four doses of polio vaccine, one dose of measles vaccine, three doses of pneumococcal vaccine, two doses of rotavirus vaccine, and one dose of yellow fever vaccine
[3] BCG, measles, and three doses each of pentavalent (DPT-HepB-Hib) and polio vaccine (excluding polio vaccine given at birth)

Table 10.3.2 shows the percentage of children age 24-35 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), and the percentage with a vaccination card by background characteristics. Large differences in coverage of age-appropriate vaccinations are observed at the level of regions; the lowest percentage of children with age-appropriate vaccination coverage is in the Central region (18 percent) and the highest is in the Greater Accra region (48 percent). Age-appropriate vaccination coverage generally increases somewhat with increasing education. The proportion of children with age-appropriate vaccination does not vary markedly with sex, birth order, residence, or mother's wealth quintile.

Overall, 80 percent of mothers of children 24-35 months had the children's vaccination card seen by interviewers, lower than for children age 12-23 months (88 percent), probably due to the misplacement or wear and tear of older children's cards.

Table 10.3.2 Vaccinations by background characteristics: Children 24-35 months

[1] Polio 0 is the polio vaccination given at birth.
[2] BCG, three doses of pentavalent (DPT-HepB-Hib) vaccine, four doses of polio vaccine, two doses of measles vaccine, three doses of pneumococcal vaccine, two doses of rotavirus vaccine, and one dose of yellow fever vaccine

10.3 TRENDS IN VACCINATION COVERAGE

Table 10.4 shows, among children age 12-59 months at the time of the survey, the percentage who received specific vaccines by age 12 months and the percentage with a vaccination card. Sixty-four percent of children age 12-59 months received all their vaccinations by age 12 months. Children in the oldest cohort (48-59 months) are less likely to have received all their vaccinations (55 percent) than children age 12-23 months (71 percent). This pattern is seen with each vaccine but is more marked when all the vaccines are considered together. Vaccination cards were shown to interviewers for 88 percent of children age 12-23 months, compared with 67 percent of children age 48-59 months. The difference may partly result from cards for older children having been lost or misplaced over the longer period of time. This difference is similar to findings in the 2008 GDHS, where 86 percent of children age 12-23 months and 60 percent of children age 48-59 months had their cards seen. Overall, vaccination cards were shown to interviewers for 77 percent of children age 12-59 months, an improvement over 2008 where cards were shown to interviewers for 73 percent of children.

The findings from the 2014 GDHS support a trend towards increasing vaccination coverage for children 12-23 months from 1988. However, the percentage of fully immunised children dropped from 79 percent in 2008 to 77 percent in 2014 (Figure 10.1). On the contrary, the coverage for various vaccines has marginally improved over the 2008 coverage levels. Immunisation coverage has improved among children of mothers with a secondary or higher education (83 percent in 2014 compared with 74 percent in 2008). Immunisation coverage also improved among children of mothers with no education (76 percent in 2014 compared with 73 percent in 2008). This notwithstanding, there were decreases in vaccination coverage. The most notable declines were among children in the Western region (from 82 percent in 2008 to 69 percent in 2014), in the Ashanti region (from 85 percent in 2008 to 79 percent in 2014), and among children in highest wealth quintile (from 84 percent in 2008 to 76 percent in 2014).

Table 10.4 Vaccinations in first year of life

Percentage of children age 12-59 months at the time of the survey who received specific vaccines by age 12 months, the percentage ever with a vaccination card, and the percentage with a vaccination card seen, by current age of child, Ghana 2014

Age in months	BCG	Pentavalent			Polio[1]				Measles 1	Pneumococcal			Rotavirus		Yellow fever	All basic vaccina-tions[2]	No vaccina-tions	Percent-age ever with a vaccina-tion card	Percent-age with a vaccina-tion card seen	Number of children

12-59	95.7	95.0	91.4	81.6	76.3	95.6	89.4	76.4	81.2	59.2	55.9	48.5	56.6	53.1	77.2	63.6	2.5	98.4	76.7	4,268

Note: Information was obtained from the vaccination card or if there was no written record, from the mother. For children whose information is based on the mother's report, the proportion of vaccinations given during the first year of life is assumed to be the same as for children with a written record of vaccinations.
[1] Polio 0 is the polio vaccination given at birth.
[2] BCG, measles, and three doses each of pentavalent (DPT-HepB-Hib) and polio vaccine (excluding polio vaccine given at birth)

The percentage of children age 12-23 months who are fully immunised has increased over the past twenty-five years, from 47 percent in 1988 to 77 percent in 2014. However, the percentage of children fully immunised has declined slightly between 2008 and 2014 from 79 percent to 77 percent (Figure 10.1).

Figure 10.1 Trends in basic vaccination coverage among children 12-23 months, Ghana 1988-2014

Percentage of children age 12-23 months

Note: Children age 12-23 months who received all basic vaccinations, i.e., BCG, measles, and three doses each of DPT or pentavalent (DPT-HepB-Hib) and polio vaccine (excluding polio vaccine given at birth).
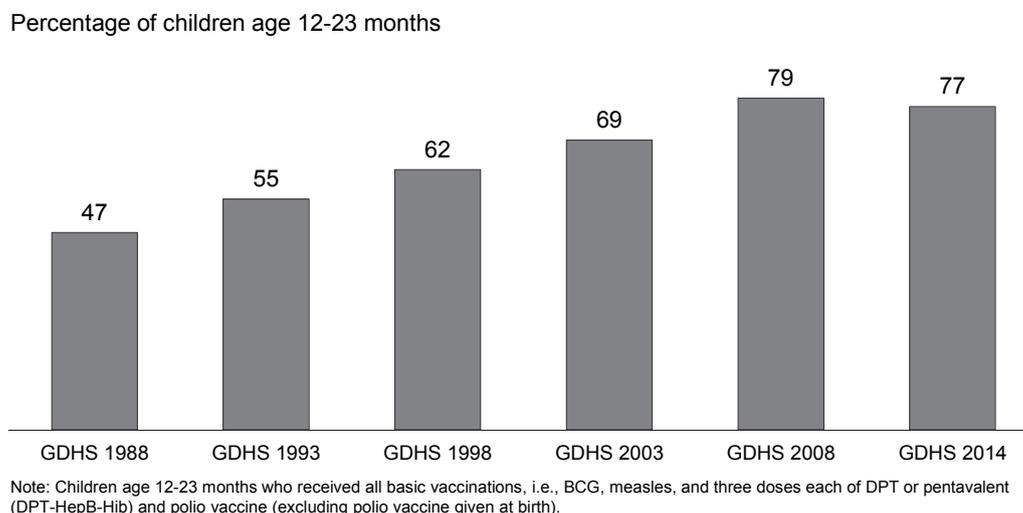

10.4 ACUTE RESPIRATORY INFECTION

Pneumonia and other respiratory tract infections are leading causes of death among young children in Ghana. In the case of pneumonia, early diagnosis and treatment with antibiotics can prevent a large proportion of deaths due to acute respiratory infections (ARIs). The prevalence of ARI in the 2014 GDHS was estimated by asking mothers whether their children under age 5 had been ill with a cough accompanied by short, rapid breathing in the two weeks preceding the survey. These symptoms, though compatible with pneumonia, are subjective (i.e., mother's perception of illness) and not validated by a medical examination. Table 10.5 shows the percentage of children under age 5 who had a cough accompanied by short, rapid breathing (symptoms of ARI).

From mothers' reports, it is estimated that 4 percent of children under age 5 had symptoms of ARI in the two weeks before the survey. A little over half of these children (53 percent) were taken to a health facility or provider (data not shown separately). This was similar to what was reported in the 2008 GDHS where half (51 percent) of the children were seen at a health facility or by a provider. There are minimal differentials in the prevalence of ARI by background characteristics, but it is worth noting that children in rural areas are almost twice as likely to have experienced symptoms of ARI as compared with children in urban areas.

Table 10.5 Prevalence and treatment of symptoms of ARI

Among children under age 5, the percentage who had symptoms of acute respiratory infection (ARI) in the two weeks preceding the survey, according to background characteristics, Ghana 2014

Middle	5.3	1,065
Fourth	2.5	1,025
Highest	2.3	1,006
Total	3.6	5,431

Note: Total includes one child for whom information on mother's smoking status is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] Symptoms of ARI (cough accompanied by short, rapid breathing that was chest-related and/or by difficult breathing that was chest-related) are considered a proxy for pneumonia.
[2] Excludes pharmacy, shop, and traditional practitioner

Treatment with antibiotics can often ameliorate the symptoms of ARI, thereby saving lives. In the 2014 GDHS, 41 percent of children under age 5 who had symptoms of ARI in the two weeks before the survey received antibiotics for their illness (data not shown).

10.5 FEVER

Fever is a sign of malaria and other acute infections in children. Malaria and other illnesses that cause fever contribute to high levels of malnutrition and mortality. While fever can occur year-round, malaria is more prevalent after the rainy season. For this reason, temporal factors must be accounted for when interpreting fever as an indicator of malaria prevalence. Malaria is a major contributory cause of death in infancy and childhood in many developing countries. A policy of presumptive treatment of fever with antimalarial medication, once advocated in many countries where malaria is endemic, was revised in Ghana in 2010. The current policy emphasises testing before treatment. Malaria in Ghana is discussed in greater detail in Chapter 12.

Table 10.6 shows the percentage of children under 5 with fever during the two weeks preceding the survey and the percentage receiving various treatments, by selected background characteristics. A little more than one-tenth (14 percent) of all children under 5 reported having fever in the past two weeks. Fever is most common among children age 12-35 months (17 percent) and is least common (4 percent) in children less than 6 months. The prevalence of fever is similar for both sexes but slightly higher for children in rural (15 percent) compared with urban (12 percent) areas. Regional differentials show that the proportion of children with fever is highest in the Upper West region (25 percent) and lowest in the Western, Central, and Greater Accra regions (11 percent each). Fever prevalence decreases slightly as mother's education increases but shows no clear relationship with wealth quintile of the mother.

Over half of the children with a fever (56 percent) were taken to a health facility or provider for treatment. Nearly half of the children with a fever took antimalarial medicines, and a quarter took antibiotics. The proportion of children who were taken to a health facility was lower for older children compared with younger children. The proportion of children who were taken to a health facility or provider was slightly higher among females (59 percent) than males (54 percent) and among rural (59 percent) than urban children (51 percent). The proportion of children under age 5 with fever for whom advice was sought from a health facility or provider was slightly higher among those whose mothers have secondary education or more compared with those whose mothers have lower education. The percentage of children who took antimalarial medicines follows similar trends as treatment sought at a health facility or with a provider.

Table 10.6 Prevalence and treatment of fever

Among children under age 5, the percentage who had a fever in the two weeks preceding the survey and among children with fever, the percentage for whom advice or treatment was sought from a health facility or provider, the percentage who took antimalarial medicines, and the percentage who received antibiotics as treatment, by background characteristics, Ghana 2014

10.6 DIARRHOEAL DISEASE

Severe diarrhoea leading to dehydration is a major cause of morbidity and mortality among young children in Ghana. Death can be prevented by administering oral rehydration therapy (ORT). Exposure to diarrhoea-causing agents is frequently related to the use of contaminated water and to unhygienic practices in food preparation and disposal of excreta. In the 2014 GDHS, mothers were asked whether any of their children under five years of age had diarrhoea during the two weeks preceding the survey. If a child had diarrhoea, the mother was asked about feeding practices during the diarrhoeal episode and what actions were taken to treat the diarrhoea. Because the prevalence of diarrhoea varies seasonally, the results of the 2014 GDHS—which relates to the fieldwork period from September to December, 2014—should be interpreted with caution.

10.6.1 Prevalence and Treatment of Diarrhoea

Table 10.7 shows the percentage of children under 5 with diarrhoea in the two weeks preceding the survey, by select background characteristics. One in ten children (12 percent) had diarrhoea during this period; 2 percent had diarrhoea with blood, which could be a sign of dysentery.

Table 10.7 Prevalence of diarrhoea

[1] See Table 2.1 for definition of categories.
[2] See Table 2.2 for definition of categories.
[3] Facilities that would be considered improved if they were not shared by two or more households

Very young children under six months are least likely to have had diarrhoea (6 percent) when compared with older children, presumably because most of them are exclusively breastfed and hence less exposed to contaminated food. Diarrhoea prevalence increases with age and peaks at 12-35 months (16-17 percent), then declines at older ages. Age 12-23 months is when children start to walk and are at increased risk of contamination from the environment. The introduction of other liquids and foods at the time of weaning can also facilitate the spread of disease-causing agents. Differences in diarrhoea prevalence by sex and by urban-rural residence are small. Children in the Brong Ahafo region have a higher prevalence of diarrhoea (17 percent) when compared with children in the other regions. Prevalence of diarrhoea is

lowest among children in the Western, Greater Accra, and Volta regions (7 percent each) and among children of mothers with a secondary or higher education (8 percent). As expected, diarrhoea prevalence is lowest among children who live in households with improved, unshared toilet facilities (5 percent), and households that are in the highest wealth quintile (7 percent). Surprisingly, diarrhoea prevalence is nearly the same among children residing in households with an improved source of drinking water (12 percent) and those residing in households where the source of drinking water is unimproved (11 percent).

Mothers of children with diarrhoea in the two weeks preceding the survey were asked what was done to manage or treat the illness. Table 10.8 shows the percentage of children with diarrhoea who were taken to a health facility or provider for treatment, the percentage who received ORT, and the percentage given other treatments, by background characteristics.

Overall, 45 percent of children with diarrhoea were taken to a health provider for treatment. Children age 12-23 months are more likely to be taken to a health facility for treatment than children of other ages. Children with bloody diarrhoea (59 percent) are more likely to be taken to a health facility for treatment compared with children with non-bloody diarrhoea (43 percent). There is no clear pattern for treatment-seeking behaviour by sex of child, and mother's education.

Oral rehydration therapy (ORT), which involves giving children with diarrhoea a solution, prepared from oral rehydration salts (ORS) or recommended home fluids (RHF)—usually a home-made sugar-salt-water solution—is a simple and effective response to diarrhoeal illness. In the 2014 GDHS, about half of children with diarrhoea were treated with either ORS or RHF (53 percent). Nineteen percent of children were given increased fluids. Children with bloody diarrhoea (63 percent) are more likely to receive ORT than children with non-bloody diarrhoea (52 percent). There is no clear variation in proportions of children likely to receive ORT by sex, residence (rural or urban), education, or wealth quintile of the child's mother.

Overall, 62 percent of children under 5 with diarrhoea were treated with ORT or increased fluids.

The MoH of Ghana has included zinc supplementation in the management of acute watery diarrhoea and dysentery in children under 5[1]. In the 2014 GDHS, only 7 percent of children with diarrhoea were given zinc supplements. Children age 12-23 months were more likely to receive zinc for diarrhoea than the other age groups. Zinc supplementation in children with diarrhoea varied very little by sex and rural-urban residence. Children with bloody diarrhoea (11 percent) were more likely to have been given zinc supplementation than those with non-bloody diarrhoea (7 percent). Children of mothers with a secondary or higher education were less likely to be given zinc supplementation compared with children of mothers with lower educational levels.

Antibiotics are generally not recommended for use in managing non-bloody diarrhoea in young children. In the 2014 GDHS, one-third of children with diarrhoea were treated with antibiotics, with a notable difference between bloody and non-bloody diarrhoea (42 percent and 32 percent, respectively). The use of antibiotics is highest among children whose mothers have the highest educational level. To the contrary, children of mothers in households in the lowest wealth quintile are more likely to receive antibiotics when they have diarrhoea. Home remedies were given to 23 percent of children with diarrhoea, and 5 percent received antimotility medicines. One in six children with diarrhoea (17 percent) was given no treatment at all.

---

[1] Excludes pharmacy, shop, and traditional practitioner

10.6.2 Feeding Practices

Mothers are encouraged to continue normal feeding of children with diarrhoea and to increase the amount of fluids given during the diarrhoeal episode. These practices help to reduce dehydration and minimise the adverse consequences of diarrhoea on the child's nutritional status, thus preventing death or complications. Mothers interviewed in the 2014 GDHS were asked whether they gave the child less, the same amount, or more fluids and food than usual when their child had diarrhoea. Table 10.9 shows the percent distribution of children under 5 who had diarrhoea in the two weeks preceding the survey by feeding practices, according to background characteristics.

Nineteen percent of children with diarrhoea were given more to drink than usual, 45 percent were given the same as usual, and 36 percent were given less to drink (i.e., somewhat less and much less) or nothing at all. It is particularly disheartening that 18 percent of children with diarrhoea were given much less to drink or nothing to drink. This is a retrogression from the 2008 GDHS, where 38 percent of children with diarrhoea were given more to drink than usual and 10 percent were given much less to drink or nothing to drink. Giving extra fluids to children with diarrhoea does not vary substantially by background characteristics; however, children whose mothers have no education were the least likely to receive more fluids compared with children of mothers with primary education or better.

As in the 2008 GDHS findings, food intake is curtailed even more than fluid intake during episodes of diarrhoea. Only five percent of children with diarrhoea were given more to eat than usual, 37 percent were given the same amount of food as usual, and 53 percent were given less food to eat than usual or nothing at all. These patterns reflect a gap in practical knowledge among some mothers regarding the nutritional requirements of children during diarrhoeal episodes. These findings are similar to the 2008 GDHS and reveal a need for further efforts on education and behaviour change communication in order to reduce the number of children that become dehydrated and/or malnourished because of improper fluid and feeding practices during diarrhoea.

Overall, 12 percent of children with diarrhoea were given increased fluids and continued feeding, and 42 percent were given increased fluids, continued feeding, and ORT. There are no marked differentials in these indicators by background characteristics; however, there was an increase in both indicators with increasing wealth quintile.

Table 10.9 Feeding practices during diarrhoea

Percent distribution of children under age 5 who had diarrhoea in the two weeks preceding the survey by amount of liquids and food offered compared with normal practice, the percentage of children given increased fluids and continued feeding during the diarrhoea episode, and the percentage of children who continued feeding and were given ORT and/or increased fluids during the episode of diarrhoea, by background characteristics, Ghana 2014

Note: It is recommended that children should be given more liquids to drink during diarrhoea, and food should not be reduced. Figures in parentheses are based on 25-49 unweighted cases.
[1] Continued feeding practices include children who were given more, same as usual, or somewhat less food during the diarrhoea episode.

10.7 KNOWLEDGE OF ORS PACKETS

A simple and effective response to dehydration caused by diarrhoea is a prompt increase in the child's fluid intake through some form of ORT, which may include the use of a solution prepared from packets of oral rehydration salts (ORS). To ascertain how widespread knowledge of ORS is in Ghana, mothers were asked whether they know about ORS packets.

Table 10.10 shows the percentage of mothers with a live birth in the five years preceding the survey who know about ORS packets for treatment of diarrhoea, by background characteristics. Knowledge of ORS among mothers is near universal in Ghana, with 95 percent of mothers having heard of it. Although knowledge does not vary profoundly with background characteristics, younger mothers are

slightly less likely to know about ORS than older mothers. Knowledge of ORS is slightly lower in Northern (86 percent) and Upper West (88 percent) regions compared with other regions (94-98 percent). ORS knowledge is slightly higher among urban mothers (98 percent) compared with rural mothers (93 percent), and it increases with education and wealth quintile.

Table 10.10 Knowledge of ORS packets

10.8   STOOL DISPOSAL

If human feces are left uncontained, diseases can spread by direct contact or by animal contact with the feces. Hence, the proper disposal of children's stools is important in preventing the spread of disease. Disposal is safe if the child used the toilet or latrine, stools are rinsed into toilet or latrine, or stools are buried. Table 10.11 shows the percent distribution of mothers who have their youngest child under age 5 living with them, by the way in which the child's stools are disposed of, according to background characteristics and type of toilet facilities in the household.

The most common method of disposing of young children's stools is throwing stools into the garbage (47 percent), followed by rinsing into a toilet or latrine (27 percent). Eight percent of children are using a toilet or latrine, and 5 percent of children have their stools left in the open (not contained). Overall, only 40 percent of mothers safely dispose of young children's stools safely; a reduction from that reported in the GDHS 2008 (48 percent).

There are differences in the way children's stools are disposed of, according to background characteristics. For example, older children are much more likely than younger children to have their stools disposed of safely. As expected, children living in households with an improved, unshared toilet facility (59 percent) and children in urban areas (43 percent) are more likely to have safe disposal of their stools

than those in households without improved toilet facilities (30 percent) and children in rural areas (37 percent). By region, the proportion of children whose stools are disposed of safely ranges from 10 percent in the Northern region to 61 percent in the Eastern region. Safe disposal of children's stools increases with mother's level of education and household wealth quintile.

Table 10.11 Disposal of children's stools

Percent distribution of youngest children under age 5 living with the mother by the manner of disposal of the child's last faecal matter, and percentage of children whose stools are disposed of safely, according to background characteristics, Ghana 2014

[3] Facilities that would be considered improved if they were not shared by two or more households

10.9 CHILDHOOD EARLY LEARNING AND DEVELOPMENT

Child development refers to the biological, psychological, and emotional changes that occur in human beings between birth and the end of adolescence, as the child progresses from dependency to increasing autonomy. According to the Children's Act (Act 560) of 1998, children are not to be deprived access to education and other activities required for their development. During these formative years, it is important to build the child's confidence and desire to learn, and expose him or her to the different aspects of learning in both academic and non-academic areas, so that the child will have a well-rounded primary

education. The children should also be exposed to a range of activities at home, in school, and in the community for them to discover their talents and interests.

This section presents focus on children age 4-15. It presents information on how parents and household members engage and support children's learning and development, as well as on the mode of travel and time it takes for children to get to school.

10.9.1 Support for Learning

Placing children in school is an important decision parents take. Such a decision could be more beneficial if parents also take interest in children's school activities while at home. The involvement of parents and other adult household members in children's school work has important effects on the children's development. The confluence of developmental and contextual changes in the early adolescence increases the risk that students may not reach their potential and heightens the need to identify sources of support. Thus, adult participation in activities with children, availability of books in the home for the child, and the conditions of care are important indicators of learning support (Hill and Tyson 2009).

Instruction in the classroom is only one piece of the educational system. All stakeholders involved in education, including parents and community members, need to work together to help students improve their learning outcomes. These include the involvement of adults with children in the following activities: helping with homework, buying or borrowing books to read, taking the child to the library, taking the child to a reading event, talking to the child's teacher about learning progress, participating in parent teacher association and school management committee activities, regularly reading to the child, encouraging child to read, communicating high expectations to the child, providing the child with a lantern/torch/lamp, and relieving the child of some household chores or other activities.

Table 10.12 presents information about the different types of learning support that household members provided to children age 4-15 in that household during the last seven days preceding the survey. The data indicate that the mean number of activities that household adult members engage in with children is about four.

Thirty-five percent of the children engaged in one to three activities with an adult household members in the past week. More than half of children age 4-15 (51 percent) were engaged by an adult household member in four or more activities that support learning. Generally, children in urban areas (56 percent) are more likely than their rural counterparts (46 percent) to engage in four or more learning activities with household members. Significant differentials by region and socio-economic status are also observed: engagement of household members in four or more activities with children is highest in Western, Greater Accra, Eastern and Central (55-57 percent) and lowest in Upper East (38 percent). While 67 percent of children living in the richest households get engaged in four or more activities with household members, the proportion of those living in the poorest households is 36 percent. Engagement of household members in activities with children increases with parents'/caretakers' education and increasing wealth. Whereas the mean number of activities for children whose parents have a secondary or higher education is five, that of children whose parents have no education is three.

Some of the activities, such as helping with homework, talking to the child's teacher about progress, participating in parent-teacher and school management committee activities, and providing the child with a lantern, torch, or lamp, only apply to children currently in school. Data in Table 10.12 on activities that promote learning can be recalculated for only those children age 4-15 who attended school during the 2014-2015 school year. In that case, the proportion of children engaged by an adult household member in four or more activities to support learning increased from 51 percent among all children to 58 percent among children of the same age attending school (data not shown). However, the percentage of children engaged in one to three activities with an adult household member in the past week is almost the same for all children age 4-15 (35 percent) and for those children age 4-15 who attended school during the 2014-2015 school year (34 percent, data not shown). The mean number of activities that household adult

members engage in with children is about four in both groups of children regardless of whether they attended school (data not shown).

Table 10.12 Activities that promote learning

Percentage of children age 4-15 with whom a household member engaged in activities that promote learning in the past in the seven days, by background characteristics, Ghana 2014

[1] Activities include helping with homework, buying or borrowing books to read, taking child to library, taking child to a reading event, talking to child's teacher about child's learning progress, participating in parent teacher association, participating in a school management committee, regularly reading to the child, encouraging the child to read, communicating high expectations to the child, providing the child with a lantern/torch/lamp, relieving the child of some household chores, or other similar activities.

10.9.2 Reading, Book Ownership, and Textbook and Reading Materials

The importance of being able to read is widely accepted. The ability to read is associated with improved quality of life, not only for the individual, but in the case of adults, also for their families and communities. Students who learn to read within the first few years of school have a greater chance of succeeding in and completing primary school.

There is evidence that children benefit most from regular reading that includes sensitive, responsive and language-rich interactional routines (Dickinson et al. 2012). As parents read with children, they have the opportunity for frequent, sensitively tuned, language-rich interactions that draw children into conversations about books, the world, language, and concepts. Allocating time to practice reading is an important way that parents and other community members can assist with building a child's reading skills.

It is important to note that the most fundamental issue relating to the impact of reading on children is reading frequency.

Table 10.13 provides information about the frequency that household members read to children age 4-15 years in the household. Overall, about one-fifth (22 percent) of children age 4-15 are living in households where a member reads to them a few times a week. About 17 percent of children are read by a household member once a week. Fifty-six percent of the children had no member of the household read to them.

The proportion of urban children who got a member of the household read to them a few times a week is higher than their rural counterparts (29 percent and 17 percent, respectively). Regional differences are observed in the proportion of children who live in households where someone reads to them a few times a week, ranging from 31 percent in Greater Accra to 11 percent in Upper West. This percentage increases substantially with parents'/caretakers' education and household wealth.

Table 10.13 also presents information about the availability of children's books and reading materials in the household. Overall, 62 percent of the children age 4-15 years live in households that had between 1 and 10 children's books and reading materials in the house, 11 percent have 11 to 20 books, and 5 percent had 21 or more books.

However, about one-fifth of children lived in households without any children's books and reading materials. The percentage of children age 4-15 living in households without any children's books and reading materials is highest in Upper West (45 percent) and lowest in Ashanti (16 percent).

By urban-rural residence, children in urban areas are more likely than those in rural areas to own books and reading materials and to own more of them. Substantial differences are observed by parent's/caretaker's education, wealth and ownership of books. One-third of children whose parents have no education have no children's books and reading material at the house compared with 7 percent of children whose parents have a secondary or higher education. A similar pattern is observed by household wealth.

Table 10.13 Reading and book ownership

Percent distribution of children age 4-15 by how often a household member reads to the child and by the number of children's books and reading materials present in the house at the time of the survey, according to background characteristics, Ghana 2014

Background characteristic	Frequency that a household member reads to children age 4-15							Number of children's books and reading materials present in the house at the time of the survey						Number of children age 4-15

Note: Total includes 1 child for whom information on mother's/father's/caretaker's education is missing.

The frequency with which children bring their reading materials home can widen their reading experience. Parents have a vested interest in their child's reading as it holds the key to other areas of learning and life. It is possible to improve student outcomes with materials that support and build students' emerging literacy skills. The more opportunities children have to read stories and other teaching and learning materials, the quicker they will learn to read. Even though the school will take steps to help the children to develop the skills needed to become a confident reader, parents play an important part by supporting and encouraging their children.

Exposure to books in early years plays an essential role in children's emerging ability to interpret the meanings of words and provides the child with greater understanding of the nature of the print. The presence of books is important for later school performance and IQ scores. Evidence suggests that the simple act of providing books to families can increase the frequency of reading and may have beneficial effects on interactions around books (Dickinson et al. 2012). It is possible to improve student outcomes with materials that support and build students' emerging literacy skills. The more opportunities children have to read stories and other teaching and learning materials, the quicker they will learn to read.

Table 10.14 provides information about how often children bring their textbooks and other reading materials home from school. The data show that 18 percent of children age 4-15 who were attending school always brought reading materials home and 17 percent of the children brought reading materials home often. Almost 3 in 10 children (29 percent) never brought any reading material home from school.

Irrespective of frequency, younger children (age 4-6) are less likely than the older children (13-15 years) to always bring reading materials home. Urban and female children are more likely to bring reading materials home from school frequently than rural and male children. Regional disparities exist with respect to the frequency with which children bring home reading materials. Children in Greater Accra region (31 percent) are the most likely to always bring home reading materials, whereas children in Upper West are the least likely to do so (4 percent). Children whose parents have a secondary or higher education and those who live in the wealthiest households are generally more likely than other subgroups to bring home reading materials frequently.

Table 10.14 Textbooks and reading materials

Among children age 4-15 who attended school during the 2014-2015 school year, percent distribution of the frequency of bringing home textbooks and other reading materials from school, according to background characteristics, Ghana 2014

10.9.3 Language for Education

The opportunity for children to use their local language has implications for their educational and cognitive development. It is argued that the use of a language other than the child's local language in education threatens their academic development and deprives them of many social advantages. However, formulating and implementing language policies of education in Ghana especially at the lower primary level has been a contentious issue at social and political levels. Parents have expressed different opinions regarding the language of instruction to be used in primary schools in the country. One school of thought suggests the use of English only as the language of instruction, while others have proposed the use of the local languages and yet some think a combination of both the English and local languages will suffice.

In Ghana, the language of instruction at lower primary school level is English combined with the local language, while that of the upper primary is English. For those who propose the use of local languages, using the mother tongue in early education will lead to a better understanding of the curriculum content and to a more positive attitude towards school. However, opponents to this idea think that it will be very costly and also be impossible to draw up a uniform code of instruction as there are more than 40 local languages in the country.

Table 10.15 shows that for 58 percent of children age 4-15, household respondents want the children to be taught in both English and a local language, for 35 percent of children household respondents want them to be taught in English only, and for only 6 percent household respondents want children to be taught in a local language only.

The percentage of children living in households where household respondents want them to be taught in both English and a local language is slightly higher in urban than in rural areas (59 percent and 57 percent, respectively). Household respondents' preference for teaching children in English and a local language is highest among children living in Volta region (70 percent), children whose parents have a secondary or higher education (60 percent), and those living in the wealthiest households (62 percent).

Table 10.15 Language for education

Percent distribution of children age 4-15 by the language in which the household respondent wants the child to be taught in, according to background characteristics, Ghana 2014

10.9.4 Travel to school

Being able to move from home to school with ease is important for the child. Each day during the school term pupils and their parents travel from home to school in the morning and make the return trip later in the day. Many pupils living close to school walk, with those living farther away travelling mainly by bus or car.

Table 10.16 shows that the majority of children age 4-15 years who attended school in the 2014-2015 school year (82 percent) walked to school, 15 percent of the children commuted to school by bus or car, and 2 percent went to school on bicycle. As expected, younger children age 4-6 years are less likely to walk to school than older children (78 percent compared with 83-84 percent). Similarly, older children age 13-15 are more likely than younger children age 4-6 to go to school by bicycle (3 percent and 1 percent, respectively). To the contrary, younger children age 4-6 are more likely than older children age 13-15 to go to school by bus or car (19 percent versus 13 percent).

In terms of residence, nearly 9 in 10 children in rural areas and more than 7 in 10 children in urban areas went to school on foot. Children in Upper West (94 percent) are the most likely to walk to school and those in Ashanti (73 percent) are the least likely to do so.

Table 10.16 also shows that children whose parents/caretakers have no education are more likely than those whose parents/caretakers have a secondary or higher education to walk to school (93 and 63 percent, respectively). Similarly, the percentage who walk to school is highest among children from the poorest households (95 percent) and lowest among those living in the wealthiest households (58 percent).

The distance between home and school, and the ease with which pupils can access transport to school, often affects a child's ability to attend school regularly. A child who is already tired before beginning classroom activities will find it difficult to comprehend the learning activities. Data show that 68 percent of school children age 4-15 travel for less than 20 minutes to get to school. About one-third spend more than 20 minutes to get to school: 24 percent spend 21-40 minutes, and 8 percent spend more than 40 minutes.

Generally, older children spend a longer time to get to school than younger children. Three-quarters of school children in Brong Ahafo (75 percent) traveled to school for less than 20 minutes compared with about half (54 percent) of children in Upper West.

Table 10.16 Travel to school

Percent distribution of children age 4-15 who attended school in the 2014-2015 school year by the usual mode they get to school and the time it takes to get to school, according to background characteristics, Ghana 2014

NUTRITION OF CHILDREN AND WOMEN

11

<div>

Key Findings:

- Among Ghanaian children under age 5 at the time of the survey, 19 percent were stunted (short for their age), 5 percent were wasted (thin for their height), and 11 percent were underweight (thin for their age). About 3 percent of children were overweight (heavy for their height).
- Almost all children in Ghana (98 percent) are breastfed at some point in their life. Fifty-two percent of children younger than 6 months were exclusively breastfed. The median duration of exclusive breastfeeding is about four months.
- Seventy-three percent of breastfed children had been given complementary foods by age 6-9 months.
- Only 13 percent of children age 6-23 months meet the minimum standards set by three core infant and young child feeding (IYCF) practices.
- Micronutrient malnutrition is highly prevalent and persistent; 66 percent of children age 6-59 months are anaemic, 27 percent are mildly anaemic, 37 percent are moderately anaemic, and about 2 percent are severely anaemic.
- Forty-two percent of Ghanaian women age 15-49 are anaemic, a reduction from 59 percent in 2008.
- Sixty-six percent of the surveyed households have iodised salt and 39 percent have adequately iodised salt (15+ ppm).

</div>

This chapter focuses on the nutritional status of children and adults in Ghana. In the 2014 GDHS survey, height and weight measurements were collected from eligible women, men, and children age 0-59 months in the subsample of households selected for the male survey (half of all households).The chapter shows the nutritional status of children under 5; infant and young child feeding practices, including breastfeeding and feeding with solid/semi-solid foods; diversity of foods fed and frequency of feeding; and micronutrient status, supplementation, and fortification. The discussion also covers the nutritional status of women and men age 15-49.

Adequate nutrition is critical to children's growth and development. The period from birth to age 2 is especially important for physical, mental, and cognitive growth, health, and development. This period is, however, often marked by poor infant and young child feeding practices that result in poor nutrition, including micronutrient deficiencies and repeated episodes of infection that interfere with optimal growth. Childhood illnesses such as diarrhoea and acute respiratory infections (ARIs) are also common. Adequate provision of nutrients, beginning in early stages of life, is crucial to ensure good physical and mental development and long-term health.

A woman's nutritional status has important implications for her health and that of her children. Malnutrition in women results in reduced productivity, increased susceptibility to infections, and slowed recovery from illness. Low body mass index and short stature, anaemia, or other micronutrient deficiencies results in increased risk of complications in pregnancy including poor foetal development, a heightened risk of adverse pregnancy outcomes, and death from postpartum haemorrhage.

11.1 NUTRITIONAL STATUS OF CHILDREN

The anthropometric data on height and weight collected in the 2014 GDHS permit the measurement and evaluation of the nutritional status of young children in Ghana. This evaluation allows identification of subgroups of the child population that are at increased risk of faltered growth, disease, impaired mental development, and death. Marked differences, especially with regard to height-for-age, weight-for-height, and weight-for-age, are often seen among subgroups of children within the country.

11.1.1 Measurement of Nutritional Status among Young Children

The 2014 GDHS collected data on the nutritional status of children under 5 by measuring their height and weight. Measurements were done in the subsample of households selected for the male survey and biomarker collection, regardless of whether the children's mothers were interviewed in the survey. Data were collected to calculate three indices: height-for-age, weight-for-height, and weight-for-age. Weight measurements were obtained using a SECA 878 digital scale, designed for weighing children and adults. Height measurements were carried out using a Shorr Productions measuring board. Children younger than 24 months were measured lying down on the board (recumbent length), and standing height was measured for older children.

Indicators of the nutritional status of children were calculated using new growth standards published by the World Health Organization (WHO) in 2006. These new growth standards were generated through data collected in the WHO Multicenter Growth Reference Study (WHO 2006). The findings of that study, which sampled 8,440 children in six countries (Brazil, Ghana, India, Norway, Oman, and the United States), describe how children should grow under optimal conditions. The WHO child growth standards can therefore be used to assess children all over the world, regardless of ethnicity, social and economic influences, and feeding practices. The new growth standards replace the previously used NCHS/CDC/WHO reference standards. The three indices are expressed in standard deviation units from the Multicenter Growth Reference Study median.

Each of these indices—height-for-age, weight-for-height, and weight-for-age—provides different information about growth and body composition that can be used to assess nutritional status. The height-for-age index is an indicator of linear growth retardation and cumulative growth deficits. Children whose height-for-age Z-score is below minus two standard deviations (-2 SD) from the median of the reference population are considered short for their age (stunted), or chronically malnourished. Children who are below minus three standard deviations (-3 SD) are considered severely stunted. Stunting reflects failure to receive adequate nutrition over a long period and is also affected by recurrent and chronic illness. Height-for age, therefore, represents the long-term effects of malnutrition (specifically, undernutrition) in a population and is not sensitive to recent, short-term changes in dietary intake.

The weight-for-height index measures body mass in relation to body height or length and describes current nutritional status. Children whose Z-scores are below -2 SD from the median of the reference population are considered thin (wasted), or acutely malnourished. Wasting represents the failure to receive adequate nutrition in the period immediately preceding the survey. It may result from inadequate food intake or a recent episode of illness causing loss of weight and the onset of malnutrition. Children whose weight-for-height is below -3 SD are considered severely wasted.

Overweight and obesity are other forms of malnutrition that are becoming concerns for some children in developing countries. Children whose Z-score values are +2 SD above the median for weight-for-height are considered overweight.

Weight-for-age is a composite index of height-for-age and weight-for-height. It takes into account both acute and chronic malnutrition. Children whose weight-for-age is below -2 SD from the median of the reference population are classified as underweight. Children whose weight-for-age is below -3 SD from the median are considered severely underweight.

Z-score means are also calculated as summary statistics representing the nutritional status of children in a population. These mean scores describe the nutritional status of the entire population without the use of a cut-off. A mean Z-score of less than 0 (i.e., a negative value for stunting, wasting, or underweight) suggests that the distribution of an index has shifted downward and, on average, children in the population are less well-nourished than children in the WHO Multicentre Growth Reference Study.

11.1.2 Data Collection

Height and weight measurements were obtained for 3,118 children under age 5 who were present in the 2014 GDHS sample households at the time of the survey. The nutritional status report covers the 97 percent of children for whom complete and credible anthropometric and age data were collected. The analysis of the anthropometric data on height and weight allows the evaluation of the nutritional status of young children and the identification of subgroups of the child population that are at increased risk of faltered growth, disease, impaired mental development, and death.

11.1.3 Levels of Child Malnutrition

Table 11.1 and Figure 11.1 show the percentage of children under 5 classified as malnourished according to the three anthropometric indices of nutritional status (height-for-age, weight-for-height, and weight-for-age). Overall, at the time of the 2014 GDHS, 19 percent of children were stunted, 5 percent were wasted, and 11 percent were underweight.

Height-for-age

Analysis by age group shows that stunting peaks in children age 24-35 months (28 percent) and is lowest (6 percent) in children age 6-8 months (Figure 11.1). Both stunting and severe stunting are slightly higher in male children (20 percent and 5 percent, respectively) than in female children (17 percent and 5 percent, respectively). Children with a preceding birth interval shorter than 24 months are at the highest risk of being stunted (29 percent) when compared with the first-born children and children with a preceding birth interval longer than 24 months. Forty percent of children whose size at birth was reported by mothers to be very small are stunted, which is twice the national average of stunting. Children in rural areas are more likely to be stunted (22 percent) than those in urban areas (15 percent). Regional variations are apparent, with stunting prevalence being the highest in Northern region (33 percent) and the lowest in the Greater Accra region (10 percent). Mother's educational level generally has an inverse relationship with children's stunting: the proportion of stunting declines drastically from 26 percent among children of mothers with no education to only 4 percent among children whose mothers have a secondary or higher education. A similar inverse relationship is observed between household wealth and stunting levels. Children in the poorest households are almost three times as likely to be stunted as children in the wealthiest households (25 percent versus 9 percent).

Weight-for-height

Table 11.1 indicates that wasting is highest in children 9-11 months (11 percent) and lowest in children 36-47 months (1 percent). Female children are more likely to be wasted (5 percent) than male children (4 percent). As is the case with stunting, children who were reportedly very small at birth are most likely to be wasted (8 percent) when compared with other children. By residence, children residing in urban areas are slightly less likely to be wasted than children in rural areas (4 percent versus 6 percent). Wasting levels in children across regions exist, ranging from a low of 3 percent among children in Volta to 9 percent among children in Upper East. There is no clear correlation between other background characteristics such as mother's education or wealth and wasting levels.

Table 11.1 Nutritional status of children

Percentage of children under 5 classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by background characteristics, Ghana 2014

Note: Table is based on children who stayed in the household on the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the WHO Child Growth Standards adopted in 2006. The indices in this table are NOT comparable to those based on the previously used NCHS/CDC/WHO reference. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight. The total includes four children for whom information on size at birth is missing.
[1] Recumbent length is measured for children under age 2, or in the few cases when the age of the child is unknown and the child is less than 87 cm; standing height is measured for all other children.
[2] Includes children who are below -3 standard deviations (SD) from the WHO Child Growth standards population median
[3] Excludes children whose mothers were not interviewed
[4] First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval
[5] Includes children whose mothers are deceased
[6] Excludes children whose mothers were not weighed and measured, children whose mothers were not interviewed, and children whose mothers were pregnant or gave birth within the preceding 2 months. Mother's nutritional status in terms of BMI (body mass index) is presented in Table 11.10.1.
[7] For women who are not interviewed, information is taken from the Household Questionnaire. Excluded are children whose mothers are not listed in the Household Questionnaire.

In Ghana, the peak levels of low weight-for-age are found among children 18-23 months (15 percent), followed by those age 24-35 months (14 percent). There are no major differences by gender. The percentage of children who are underweight shows a strong correlation with child's size at birth as perceived by mothers.

Children born to thin mothers (BMI < 18.5) are more than four times as likely to be underweight (22 percent) as children born to mothers who are overweight/obese (5 percent). Children living in rural areas are more likely to be underweight than those in urban areas (13 percent and 9 percent, respectively). The proportion of underweight children ranges from 6 percent in the Brong Ahafo region to 20 percent in the Northern region. Children born to mothers with little or no education are substantially more likely to be underweight than children of more educated women.

Figure 11.1 Nutritional status of children by age
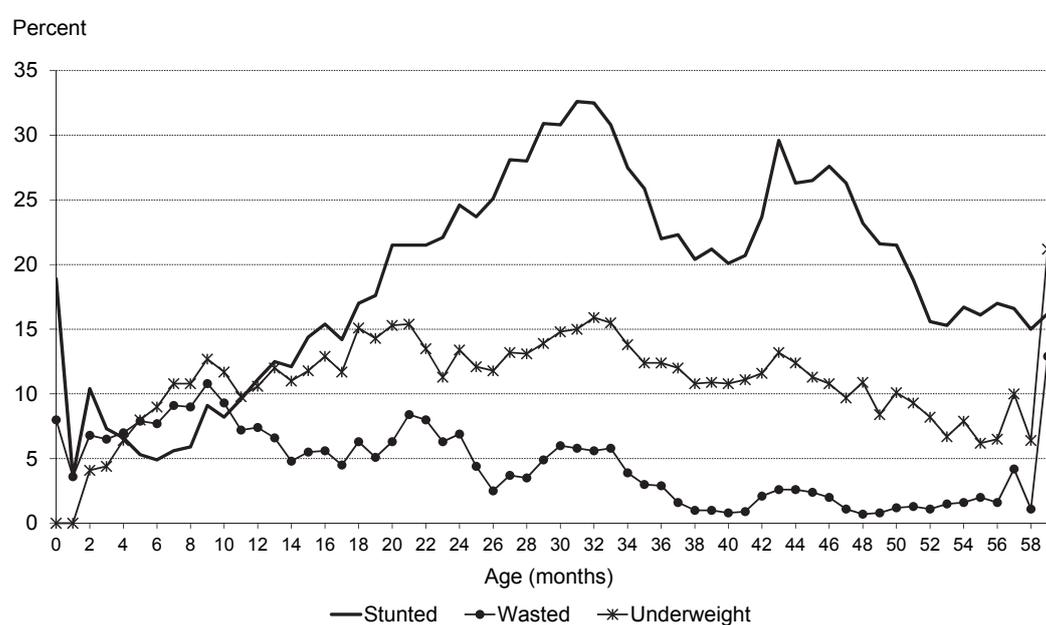

Note: *Stunting* reflects chronic malnutrition; *wasting* reflects acute malnutrition; *underweight* reflects chronic or acute malnutrition or a combination of both. Plotted values are smoothed by a five-month moving average.

GDHS 2014

11.1.4 Trends in Children's Nutritional Status

Figure 11.2 displays the trends in the proportion of children under 5 who are stunted, wasted, or underweight between the 2003 and 2014 GDHS surveys. The data show a downward trend and reveal that all three nutritional status indices have improved in the last decade.

The proportion of stunted children has decreased steadily from 35 percent in 2003 to 19 percent in 2014. The proportion of wasted children has decreased from 8 percent in 2003 and 9 percent in 2008, to 5 percent in 2014. The proportion of underweight children has decreased from 18 percent in 2003 to the current level of 11 percent. Overweight among children fluctuated between 4-5 percent between 2003 and 2008, and is currently at 3 percent.

Figure 11.2 Trends in nutritional status of children under age 5, Ghana 2003-2014

Percent

Note: *Stunting* reflects chronic malnutrition; *Wasting* reflects acute malnutrition; *Underweight* reflects chronic or acute malnutrition or a combination of both. Data are based on the WHO Child Growth Standards (2006).
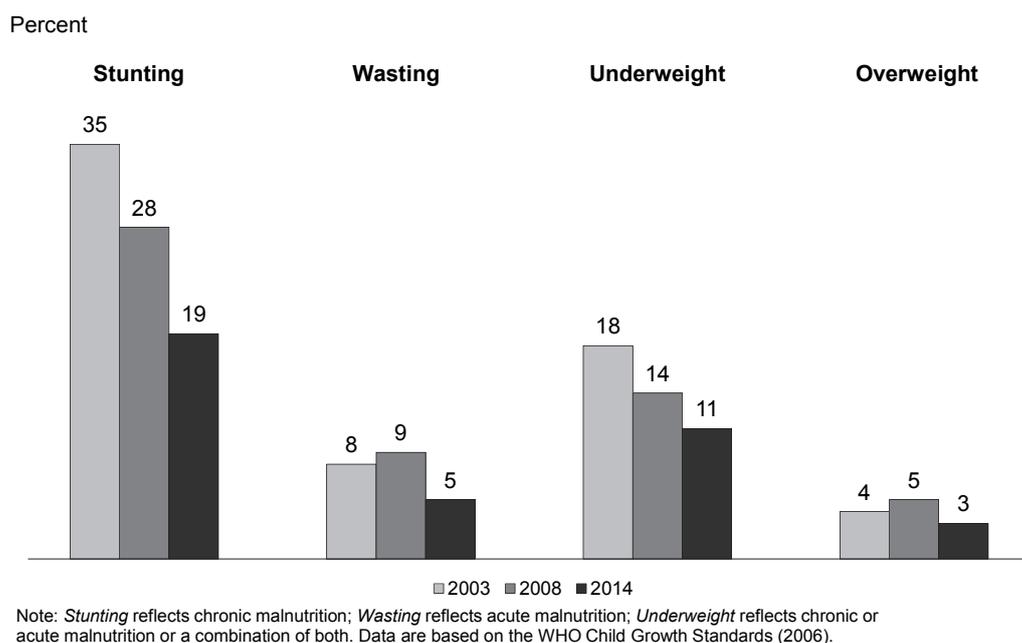

11.2 BREASTFEEDING AND COMPLEMENTARY FEEDING

Optimal feeding is critical to ensure adequate growth and child development, nutritional status, health and, thus, the survival of infants and young children. GDHS data can be used to evaluate infant feeding practices, including breastfeeding duration, introduction of complementary weaning foods, and use of feeding bottles. The pattern of infant feeding has important influences on both the child and the mother. Feeding practices are the principal determinants of a child's nutritional status. Poor nutritional status in young children exposes them to greater risks of morbidity. Biologically, breastfeeding suppresses the mother's return to fertile status and affects the length of the birth interval as well as the level of fertility. These effects are influenced by both the duration and frequency of breastfeeding and the age at which the child receives foods and liquids to complement breast milk.

11.2.1 Initiation of Breastfeeding

Early initiation of breastfeeding is important for both the mother and the child. Early suckling stimulates the release of prolactin, which helps in the production of milk, and oxytocin, which is responsible for the ejection of milk. It also stimulates contraction of the uterus after childbirth and reduces postpartum blood loss. The first milk known as colostrum, produced in the first few days after delivery, is highly nutritious and contains antibodies that provide natural immunity to the infant. It is recommended that children be fed colostrum immediately after birth (within one hour) and that they continue to be exclusively breastfed even if the regular breast milk has not yet started to flow.

Table 11.2 presents the percentage of last-born children born in the two years preceding the survey according to whether they were ever breastfed, when they began breastfeeding, and whether they were fed anything other than breast milk prior to the start of breastfeeding. Breastfeeding is almost universal in Ghana and over 98 percent of lastborn children born in the past two years preceding the 2014 GDHS have been breastfed at some point in time. The differences in any breastfeeding by background characteristic are minor.

More than half (56 percent) of children are breastfed within one hour of birth, while almost 9 in 10 (87 percent) are breastfed within one day of birth. Initiation of breastfeeding within one hour varies more

substantially by region and by the person who provided assistance at delivery. Mothers residing in Northern and Upper East regions are most likely to initiate breastfeeding within one hour of birth (65 percent each), while those in Upper West are the least likely (41 percent). Women whose births were assisted by a traditional birth attendant are the most likely to have started breastfeeding early (62 percent) and those whose deliveries were not assisted by anyone are the least likely (34 percent).

The practice of providing a prelacteal feed to the newborn is not recommended because it exposes the baby to the risk of infection and may limit the frequency of suckling by the infant, which is a key in successful establishment of breastfeeding. Among last-born children, born in the two years immediately preceding the survey who were ever breastfed, 15 percent received a prelacteal feed. The highest proportion of last-born children who received a prelacteal feed were children residing in urban areas (18 percent) and those in the wealthiest households (24 percent).

Table 11.2 Initial breastfeeding

Among last-born children who were born in the two years preceding the survey, the percentage who were ever breastfed and the percentages who started breastfeeding within one hour and within one day of birth; and among last-born children born in the two years preceding the survey who were ever breastfed, the percentage who received a prelacteal feed, by background characteristics, Ghana 2014

Note: Table is based on last-born children born in the two years preceding the survey regardless of whether the children are living or dead at the time of interview. Total includes 1 child for whom information on place of delivery is missing. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] Includes children who started breastfeeding within one hour of birth
[2] Children given something other than breast milk during the first three days of life
[3] Doctor, nurse/midwife, or community health officer/nurse

The trends data on initiation of breastfeeding indicate that the proportion of children ever breastfed has remained stable around 98 percent over the past decade. The percentage of children who started breastfeeding within one hour of birth, however, has increased from 46 percent in 2003 to 52 percent in 2008, and further to 56 percent in 2014. Giving prelacteal feed to newborns, which is discouraged, has shown a slow decline from 20 percent in 2003, to 18 percent in 2008, and to 15 percent in 2014.

11.3 BREASTFEEDING STATUS BY AGE

UNICEF and WHO recommend that children be exclusively breastfed during the first six months of life and that they be given age-appropriate solid or semi-solid complementary food in addition to continued breastfeeding from age 6 months to at least age 24 months. Exclusive breastfeeding is recommended because breast milk is uncontaminated and contains all of the nutrients necessary for children in the first few months of life. In addition, the mother's antibodies in breast milk provide immunity to diseases or infections. Early supplementation is discouraged for several reasons. First, it exposes infants to pathogens and increases their risk of infection. Second, it decreases infants' intake of breast milk and therefore suckling, which reduces breast milk production. Third, in low-resource settings, supplementary food is often nutritionally inferior.

The Ghana national IYCF strategy promotes exclusive breastfeeding through age 6 months and, thereafter, the introduction of semi-solid or solid foods along with continued breast milk until the child is at least two years old. To create the environment that will enable mothers, families, and other caregivers in all circumstances to make informed choices about optimal feeding practices in particular, work has been done to promote breastfeeding, enforce the International Code of Marketing of Breast milk Substitutes, implement maternal protection laws, and promote baby-friendly hospitals across the country.

Table 11.3 and Figure 11.3 show breastfeeding practices by child's age. Data show that duration of breastfeeding is long in Ghana; almost 9 in 10 children are breastfed until age 12-15 months. More than half (52 percent) of children under 6 months are exclusively breastfed. However, only 36 percent are continued to exclusively breastfeed at 4-5 months.

The recommended age for introduction of complementary foods is six months; almost three-quarters (73 percent) of children 6-8 months were given complementary foods. Twelve percent of children age 2-3 months and 34 percent of children age 4-5 months also received complementary foods, which is not recommended for these younger age groups.

The use of a bottle with a nipple, regardless of the contents (breastmilk, formula, or any other liquid), requires hygienic handling to avoid contamination that may place the infant at risk of infection. The survey results show that 16 percent of infants less than 6 months are fed using a bottle with a nipple; the percentage goes up to 28 percent among children age 6-9 months.

Trends data on breastfeeding indicate that the percentage of children 0-5 months who are exclusively breastfed has decreased by 17 percent between 2008 and 2014, from 63 percent to 52 percent. The percentages of young children who are bottle fed appear to have increased over the past decade. In 2003 and 2008, 11 percent and 12 percent children under 6 months, respectively, were fed with bottles with nipples; this percentage has increased to 16 percent in 2014.

Table 11.3 Breastfeeding status by age

Percent distribution of youngest children under age 2 who are living with their mother by breastfeeding status, the percentage currently breastfeeding; and the percentage of all children under age 2 using a bottle with a nipple, according to age (in months), Ghana 2014

Age (in months)	Not breast-feeding	Exclusively breastfed	Breast-feeding and consuming plain water only	Breast-feeding and consuming non-milk liquids[1]	Breast-feeding and consuming other milk	Breast-feeding and consuming comple-mentary foods	Total	Percent-age currently breast-feeding	Number of youngest child under two years living with their mother	Percent-age using a bottle with a nipple	Number of all children under two years
0-1	0.0	78.4	8.9	4.1	5.9	2.8	100.0	100.0	131	4.5	132

6-8	0.5	5.7	15.7	2.7	2.8	72.6	100.0	99.5	309	28.9	317
9-11	1.6	0.7	8.2	0.4	0.0	89.0	100.0	98.4	270	18.0	275
12-17	9.3	0.7	4.6	1.0	0.0	84.4	100.0	90.7	563	10.1	574
18-23	40.8	0.1	1.9	0.9	0.2	56.1	100.0	59.2	498	6.0	540
0-3	0.3	62.9	17.4	4.2	6.5	8.7	100.0	99.7	338	12.3	344
0-5	0.8	52.3	17.6	4.2	6.6	18.6	100.0	99.2	561	16.0	571
6-9	0.6	4.5	14.8	2.3	2.2	75.7	100.0	99.4	395	27.6	403
12-15	5.4	0.7	5.4	1.5	0.0	87.0	100.0	94.6	369	11.4	373
12-23	24.1	0.4	3.4	1.0	0.1	71.1	100.0	75.9	1,062	8.1	1,113
20-23	49.9	0.1	0.5	0.4	0.0	49.0	100.0	50.1	331	4.4	368

Note: Breastfeeding status refers to a 24-hour period (yesterday and last night). Children who are classified as breastfeeding and consuming plain water only consumed no liquid or solid supplements. The categories of not breastfeeding, exclusively breastfed, breastfeeding and consuming plain water, non-milk liquids, other milk, and complementary foods (solids and semi-solids) are hierarchical and mutually exclusive, and their percentages add to 100 percent. Thus children who receive breast milk and non-milk liquids and who do not receive other milk and who do not receive complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary food are classified in that category as long as they are breastfeeding as well.
[1] Non-milk liquids include juice, juice drinks, clear broth, or other liquids.

Figure 11.3 Infant feeding practices by age
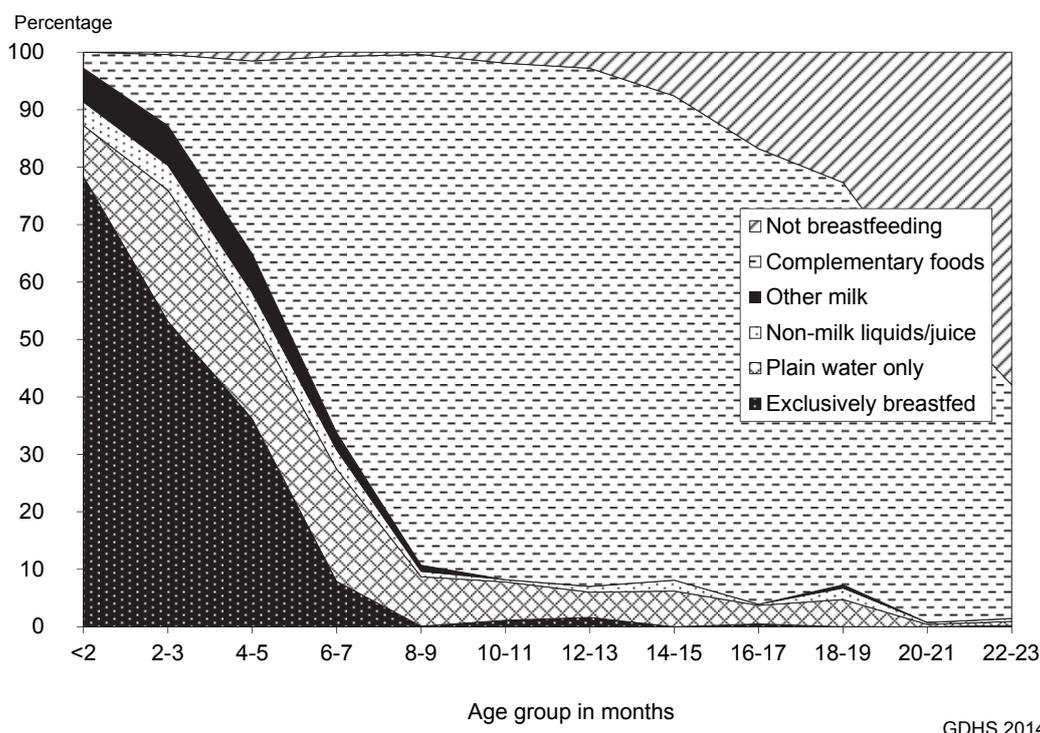

GDHS 2014

Figure 11.4 presents 2014 GDHS results on infant and young child feeding (IYCF) indicators related to breastfeeding status. Detailed descriptions of these indicators can be found in WHO publications (WHO 2008; WHO 2010). As noted previously and as shown in Figure 11.4, 52 percent of children under age 6 months and 36 percent of those age 4-5 months are exclusively breastfed. Ninety-five percent of all children are still breastfeeding at age 1, and 50 percent are still breastfeeding at age 2. Sixty-nine percent

of children age 0-23 months are breastfed appropriately for their age. This includes exclusive breastfeeding for children age 0-5 months and continued breastfeeding along with complementary foods for children age 6-23 months. More than 7 in 10 children under age 6 months (74 percent) are predominantly breastfed. This percentage includes children who are exclusively breastfed and those who receive breast milk and only plain water or non-milk liquids such as juice. Finally, 14 percent of children under age 2 are bottle fed.

Figure 11.4 IYCF indicators on breastfeeding status

Percentage of children
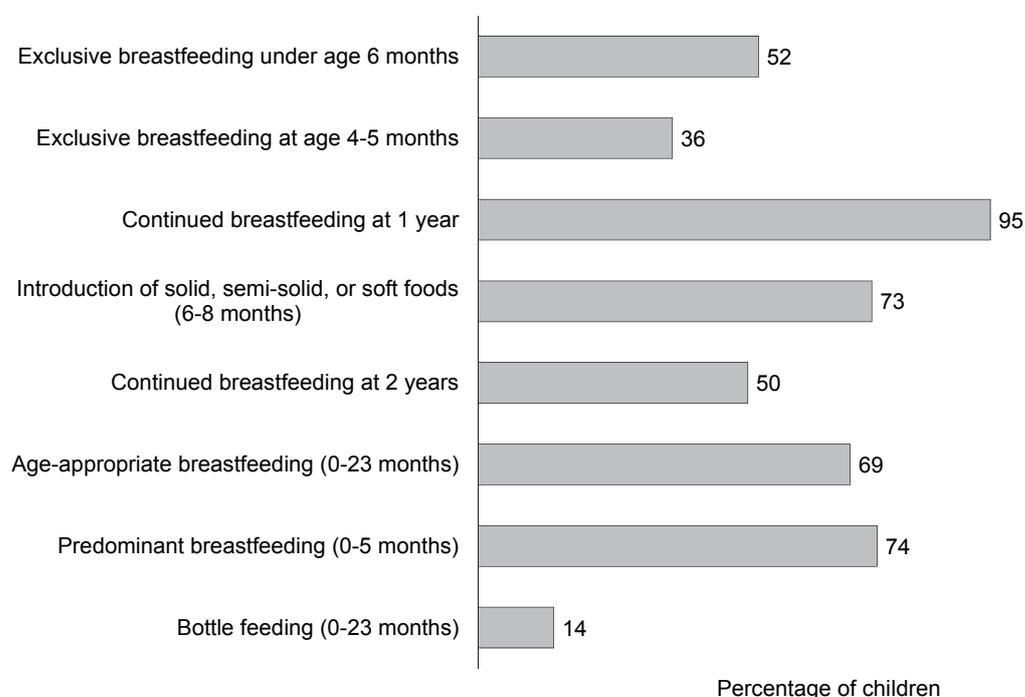

GDHS 2014

11.4 DURATION OF BREASTFEEDING

Table 11.4 provides information on the median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey. The median duration of any breastfeeding is 20.9 months and the mean duration of breastfeeding is 21.2 months. By background characteristics, the most noticeable difference in the median duration of breastfeeding is observed by wealth status, where the median duration ranges from 18.9 months in the richest households to 24.2 months in the poorest households.

The median duration of exclusive breastfeeding for all children is only 2.5 months, and the mean duration is 3.9 months, slightly lower than the figures reported in the 2008 GDHS (3.3 months and 4.4 months, respectively).

Table 11.4 Median duration of breastfeeding

Median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey, by background characteristics, Ghana 2014

Includes children living and deceased at the time of the survey. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] It is assumed that non-last-born children and last-born children not currently living with the mother are not currently breastfeeding
[2] Either exclusively breastfed or received breast milk and plain water, and/or non-milk liquids only

11.5 TYPES OF COMPLEMENTARY FOODS

After six months, a child requires adequate complementary foods for normal growth as at this age breast milk alone is no longer sufficient to maintain the child's recommended daily allowances of nutritional requirements to enhance growth. Inadequate complementary feeding may lead to malnutrition and frequent illnesses, however, which in turn may lead to death. Complementary feeding is particularly important in sub-Saharan African countries, including Ghana where stunting is highly prevalent and promotion of breastfeeding and appropriate complementary feeding could prevent growth faltering and deaths among children under age 5.

To promote optimal nutrition during this period, promote healthy growth, and foster better development particularly in the first 2 years of a child's life, the Global IYCF Strategy is adapted for and implemented in Ghana. It is intended as a framework for actions to protect, promote, and support appropriate infant and young child feeding. The comprehensive strategy consists of actions to raise awareness through counselling and to provide support for adequate complementary feeding during 6-24 months and continued breastfeeding up to 2 years.

According to Table 11.5, 88 percent of breastfed children age 6-23 months received solid or semi-solid foods in addition to breastmilk during the day or night preceding the interview. The common complementary foods provided include fortified baby foods (19 percent), foods made from grains (78 percent), fruits and vegetables rich in vitamin A (37 percent), other fruits and vegetables (18 percent), and food made from roots and tubers (26 percent). Children are also fed protein-rich foods such as legumes and nuts (12 percent); meat, fish, and poultry (48 percent); and eggs (18 percent). Only 4 percent are given other foods including cheese, yogurt, and other milk products. Liquids fed to children breastfeeding in this age group include other milk (13 percent) and other liquids (27 percent). The use of infant formula is minimal (5 percent).

Among nonbreastfeeding children age 6-23 months, almost everyone received solid or semi-solid foods the previous day. Ninety-four percent of nonbreastfeeding children received foods made from grains; almost 8 in 10 (78 percent) were given meat, fish, poultry, or eggs; 40 percent ate fruits and vegetables other than those rich in vitamin A; 60 percent ate fruits and vegetables rich in vitamin A; and 38 percent consumed food made from roots and tubers.

Table 11.5 Foods and liquids consumed by children in the day or night preceding the interview

Percentage of youngest children under age2 who are living with the mother by type of foods consumed in the day or night preceding the interview, according to breastfeeding status and age, Ghana 2014

Note: Breastfeeding status and food consumed refer to a "24-hour" period (yesterday and last night).
[1] Other milk includes fresh, tinned, and powdered cow or other animal milk.
[2] Doesn't include plain water
[3] Includes fortified baby food
[4] Includes pumpkin, carrots, squash or sweet potatoes, dark green leafy vegetables, mangoes, paw paw, and other locally grown fruits and vegetables that are rich in vitamin A

11.6 INFANT AND YOUNG CHILD FEEDING (IYCF) PRACTICES

Appropriate IYCF practices include breastfeeding through age 2, introduction of solid and semi-solid foods at age 6 months, and gradual increases in the amount of food given and frequency of feeding as the child gets older. The minimum frequencies for feeding children in developing countries are based on the energy output of complementary foods. The energy needs of children are based on age-specific total daily energy requirements plus 2 SD (to cover almost all children), minus the average energy intake from breast milk. Infants with low breast milk intake need to be fed more frequently than those with high breast milk intake. However, care should be taken that feeding frequencies do not exceed the recommended input from

complementary foods because excessive feeding can result in displacement of breast milk (PAHO/WHO 2003).

According to recommendations, breastfed children age 6-23 months should receive animal-source foods and vitamin A-rich fruits and vegetables daily (PAHO/WHO 2003). Because first foods almost always include a grain- or tuber-based staple, it is unlikely that young children who eat food from less than three groups will receive both an animal-source food and a vitamin A-rich fruit or vegetable. Therefore, three food groups are considered the minimum number appropriate for breastfed children (Arimond and Ruel 2004). Breastfed infants age 6-8 months should receive complementary foods two to three times a day, with one or two snacks; breastfed children age 9-23 months should receive meals three to four times a day, with one or two snacks. Non-breastfed children age 6-23 months should receive milk or milk products two or more times a day to ensure that their calcium needs are met. In addition, they need animal-source foods and vitamin A-rich fruits and vegetables. Four food groups are considered the minimum number appropriate for non-breastfed young children. Non-breastfed children age 12-23 months should be fed meals four to five times each day, with one or two snacks (PAHO/WHO 2003; WHO 2008; and WHO 2010).

Table 11.6 shows the percentage of children under age 2 living with their mothers who are fed according to three IYCF practices[1] based on breastfeeding status, number of food groups, and number of times fed during the day or night preceding the survey. Among breastfed children, 24 percent were given foods from at least four groups and 45 percent were fed the minimum number of times during the day and night preceding the survey. Fifteen percent of the breastfed children fall into both categories, i.e., their feeding practices meet minimum standards with respect to food diversity and feeding frequency (Table 11.6 and Figure 11.4). Regional variations exist; children living in the Central region are most likely to receive the minimum acceptable diet (27 percent), and those in the Eastern region are the least likely (4 percent). Breastfed children of educated mothers (27 percent) who reside in the wealthiest households (22 percent) are most likely to receive a quality diet.

With regards to the non-breastfed children age 6-23 months, only 11 percent were given milk or milk products an adequate number of times, almost half (49 percent) received foods from at least four food groups, and 37 percent were fed the minimum number of times. However, only 5 percent of nonbreastfeeding children feeding practices qualified as being in accordance with all three IYCF practices.

Among all children age 6-23 months, only 13 percent were fed the minimum acceptable diet. Overall, 86 percent of children received breastmilk, milk, or milk products, 28 percent received four or more food groups, and 43 percent received food the minimum number of times. Children in the 12-17 age group, those who live in urban areas and in Greater Accra, children of educated mothers, and those in the wealthiest households are most likely to receive the minimum acceptable diet. It is noteworthy that only 4 percent of children residing in the Eastern region received the minimum acceptable diet.

---

[1] It should also be noted that there have been changes in the definition of the standard IYCF indicators since 2008. Examples are the removal of "foods made with fats" as a food group, the requirement that breastfed children receive four instead of three food groups, the requirement that non-breastfed children receive two or more servings of milk or milk products, and the removal of cheese from the milk or milk products list in line with recent WHO IYCF feeding indicators guidelines. Thus, in certain instances comparison of related indicators with previous GDHS reports may be problematic.

Table 11.6 Infant and young child feeding (IYCF) practices

Percentage of youngest children age 6-23 months living with their mother who are fed according to three IYCF feeding practices based on breastfeeding status, number of food groups, and times they are fed during the day or night preceding the survey, by background characteristics, Ghana 2014

[1] Food groups: a. infant formula, milk other than breast milk, cheese or yogurt or other milk products; b. foods made from grains, roots, and tubers, including porridge and fortified baby food from grains; c. vitamin A-rich fruits and vegetables; d. other fruits and vegetables; e. eggs; f. meat, poultry, fish, and shellfish, and organ meats; g. legumes and nuts. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[2] For breastfed children, minimum meal frequency is receiving solid or semi-solid food at least twice a day for infants 6-8 months and at least three times a day for children 9-23 months
[3] Includes two or more feedings of commercial infant formula, fresh, tinned, and powdered animal milk, and yogurt
[4] For non-breastfed children age 6-23 months, minimum meal frequency is receiving solid or semi-solid food or milk feeds at least four times a day
[5] Non-breastfed children age 6-23 months are considered to be fed with a minimum standard of three Infant and Young Child Feeding Practices if they receive other milk or milk products at least twice a day, receive the minimum meal frequency, and receive solid or semi-solid foods from at least four food groups not including the milk or milk products food group
[6] Breastfeeding, or not breastfeeding and receiving two or more feedings of commercial infant formula, fresh, tinned and powdered animal milk, and yogurt
[7] Children are fed the minimum recommended number of times per day according to their age and breastfeeding status as described in footnotes 2 and 4

11.7 ANAEMIA IN CHILDREN

Anaemia is a condition characterised by a reduction in the red blood cell volume and a decrease in the concentration of haemoglobin in the blood. Haemoglobin is necessary for transporting oxygen to tissues and organs in the body. Anaemia in children is associated with impaired mental and physical development and with increased morbidity and mortality. Anaemia can be a particularly serious problem for pregnant women, leading to premature delivery and low birth weight babies. Globally, iron deficiency anaemia is the most common micronutrient deficiency, and anaemia is often described as an indicator of both poor nutrition and poor health.

The most common causes of anaemia in Ghana are inadequate dietary intake of iron, malaria, and intestinal worm infestation (GHS 2003). Iron and folic acid supplementation and antimalarial prophylaxis for pregnant women, promotion of the use of insecticide-treated bed nets by pregnant women and children under age 5, deworming at 6 months of children age 2 to 5, and food fortification are some important measures to reduce the anaemia burden among vulnerable groups.

The 2014 GDHS survey is the second DHS in Ghana to include anaemia testing of children age 6-59 months and women age 15-49, the first one being the 2008 GDHS. In the 2014 GDHS, anaemia was tested in half of the households, the same subsample that was selected for the male survey. Anaemia prevalence was determined by measuring the level of haemoglobin in the blood. For haemoglobin measurements a drop of capillary blood was taken with a finger prick (using sterile, disposable instruments), and the haemoglobin concentration was measured using the HemoCue photometer system. The results are based on tests of 2,568 (de facto) children present at the time of testing, whose parents consented to their being tested and whose haemoglobin results represented plausible data.

Sixty-six percent of children age 6-59 months in Ghana have some level of anaemia: 27 percent are mildly anaemic, 37 percent are moderately anaemic, and 2 percent are severely anaemic. Overall, prevalence of anaemia decreases with increasing age of the child. The prevalence of any anaemia is highest among children age 6-8 months (80 percent); and more than 7 in 10 children under age 2 are anaemic. Children in rural areas (72 percent) are much more likely to be anaemic compared with children living in urban areas (58 percent). Slight variations are observed in children's anaemia by region. Children

in the Northern region (82 percent) are the most likely to be anaemic, while children in the Ashanti region are the least likely to be anaemic (54 percent). The likelihood of a child having anaemia decreases with increasing mother's education and household wealth. Nevertheless, it is noteworthy that almost half of the children living in households with the most educated mothers and highest wealth quintile are anaemic.

Note: Table is based on children who stayed in the household on the night before the interview and who were tested for anaemia. Prevalence of anaemia, based on haemoglobin levels, is adjusted for altitude using formulas in CDC, 1998. Haemoglobin in grams per deciliter (g/dl).
[1] Includes children whose mothers are deceased
[2] For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

Trends data for anaemia in children indicate that prevalence increased slightly from 76 percent in 2003 to 78 percent in 2008 and decreased to 66 percent between 2008 and 2014 (Figure 11.6).

11.8 MICRONUTRIENT INTAKE AMONG CHILDREN

Micronutrient deficiency is a major contributor to childhood morbidity and mortality. Micronutrients are available in foods and can also be provided through direct supplementation. Breastfeeding children benefit from supplements given to the mother. In Ghana the prevailing levels of micronutrient deficiency levels related to anaemia, vitamin A, and iodine are considered high and of major public health significance by World Health Organisation standards.

Iron deficiency is one of the primary causes of anaemia, which has serious health consequences for both women and children. Vitamin A is an essential micronutrient for the immune system and plays an important role in maintaining the epithelial tissue in the body. Severe vitamin A deficiency (VAD) can cause eye damage and is the leading cause of childhood blindness. VAD also increases the severity of infections such as measles and diarrhoeal disease in children and slows recovery from illness. VAD is common in dry environments where fresh fruits and vegetables are not readily available. Vitamin A supplementation is an important tool in preventing VAD among young children. Iodine is an important trace element essential for the normal function of the thyroid gland. Iodine deficiency is most frequently caused by inadequate iodine intake and has serious effects on growth and mental development. The deficiency is the leading cause of preventable mental impairment worldwide.

Information was collected on food consumption during the day and night preceding the interview among the youngest children under age 2 living with their mothers; these data are useful in assessing the extent to which children are consuming food groups rich in two key micronutrients—vitamin A and iron—in their daily diet. In addition, the GDHS included questions designed to ascertain whether young children had received vitamin A supplements or deworming medication in the six months preceding the survey or iron supplements in the seven days preceding the survey.

Table 11.8 shows the intake of key micronutrients among children and shows the extent to which young children consumed adequate amounts of foods rich in vitamin A and iron by background characteristics. The results show that among the youngest children age 6-23 months living with their mother, 67 percent consumed foods rich in vitamin A on the day or night preceding the survey. There are very slight differences in consumption of vitamin A-rich foods by sex and residence. Nonbreastfeeding children are more likely to consume vitamin A-rich foods (92 percent) compared with breastfeeding children (62 percent). Mother's education shows slight association with the consumption of vitamin A-rich foods: 63 percent of children of mothers with primary education consume vitamin A-rich foods, compared with 78 percent of children of mothers with a secondary or higher education. Regional variations are evident in the consumption of vitamin A-rich foods by children, with the highest proportion being in the Central region (82 percent) and the lowest being in the Northern region (56 percent).

Nearly 7 out of 10 children age 6-23 months living with the mother consumed foods rich in iron in the 24 hours preceding the survey (67 percent). Variations by most background characteristics are similar to those observed for vitamin A-rich foods. By region, the consumption of iron-rich foods among children is highest in Central (78 percent) and lowest in Upper East (36 percent).

Table 11.8 also shows information on vitamin A and iron supplementation. Among all children age 6-59 months, 65 percent received vitamin A supplements in the six months immediately preceding the survey. Vitamin A supplementation is higher among children age 6-23 months than among older children. Breastfeeding children are more likely than nonbreastfeeding children to have received a vitamin A supplement in the last six months (72 percent and 62 percent, respectively). Children in urban areas are slightly less likely to receive a vitamin A supplement than children in rural areas (63 percent versus 68 percent). The proportion of children who received a vitamin A supplement is highest in the Central region (79 percent) and lowest in the Northern region (44 percent). There are no consistent patterns in percentage of children receiving a vitamin A supplement by mothers' education and age at birth, or by household wealth.

Regarding iron supplementation, only 24 percent of children age 6-59 months received an iron supplement in the seven days preceding the survey. There are no notable variations by most background characteristics, except for regions and household wealth. The percentage of children age 6-59 months who received an iron supplement in the seven days preceding the survey ranges from 9 percent in the Upper West to 37 percent in Western. Children from the poorest households are the least likely to have received iron supplementation in the past seven days (19 percent).

Looking at trends, the proportion of children age 6-59 months who received vitamin A supplementation in the preceding six months increased from 56 percent in 2008 to 65 percent in 2014, and the proportion who received an iron supplement in the seven days preceding the survey decreased somewhat, from 28 percent in 2008 to 24 percent in 2014.

Intestinal parasites such as helminthes can contribute to anaemia, and periodic deworming to control such organisms can improve children's health and growth. The 2014 GDHS collected information on whether children age 6-59 months had been given deworming medication in the six months before the survey. Results shown in Table 11.8 indicate that 38 percent of children age 6-59 months received deworming medication in the six months preceding the survey. Children in urban areas are more likely than those in rural areas to receive deworming medication (43 percent and 35 percent, respectively). The regional coverage of deworming medication among children ranges from a low of 13 percent in Upper West to 49 percent in Ashanti. Nonbreastfeeding children, children whose mothers have a secondary or higher education, and those from the wealthiest households are the most likely to be given deworming medication. For example, 52 percent of children who belong to the wealthiest households received deworming medication compared with only 19 percent of children from the poorest households.

Table 11.8 Micronutrient intake among children

Among youngest children age 6-23 months who are living with their mother, the percentages who consumed vitamin A-rich and iron-rich foods in the day or night preceding the survey, among all children 6-59 months, the percentages given vitamin A supplements in the six months preceding the survey, the percentages given iron supplements in the past seven days, and the percentages given deworming medication in the six months preceding the survey; and among all children age 6-59 months who live in households tested for iodised salt, the percentage who live in households with iodised salt, by background characteristics, Ghana 2014

Background characteristic	Among youngest children age 6-23 months living with the mother:			Among all children age 6-59 months:				Among children age 6-59 months living in households tested for iodised salt	
	Percentage who consumed foods rich in vitamin A in last 24 hours[1]	Percentage who consumed foods rich in iron in last 24 hours[2]	Number of children	Percentage given vitamin A supplements in past 6 months	Percentage given iron supplements in past 7 days	Percentage given deworming medication in past 6 months[3]	Number of children	Percentage living in households with iodised salt[4]	Number of children

Note: Information on vitamin A is based on both mother's recall and the immunisation card (where available). Information on iron supplements and deworming medication is based on the mother's recall. Total includes four children with missing information on breastfeeding status.
na = Not applicable
[1] Includes meat (including organ meat), fish, poultry, eggs, pumpkin, carrots, squash or sweet potatoes, dark green leafy vegetables, mangoes, paw paw, and other locally grown fruits and vegetables that are rich in vitamin A.
[2] Includes meat (including organ meat), fish, poultry, and eggs.
[3] Deworming for intestinal parasites is commonly done for helminthes and for schistosomiasis.
[4] Excludes children in households in which salt was not tested.

Ghana has adopted a national programme for universal salt iodisation (USI) to iodise salt as the main approach for the prevention of iodine deficiency. This is backed by the Food and Drugs Law Amendment Act (Act 523) passed in 1996, making provision for the mandatory fortification of all refined and unrefined edible salt with potassium iodate. To generate data on household use or consumption of iodised salt a semi-quantitative rapid test kit was used to measure iodine content of the salt used for cooking in a selected household subsample.

Table 11.8 shows that 62 percent of children live in households that use iodised salt. Children in urban areas (69 percent) are more likely to live in households that use iodised salt than their rural counterparts (56 percent). The percentage of children living in households that use iodised salt is lowest in the Eastern region (39 percent) and highest in the Western region (80 percent). Almost 8 in 10 children who are born to mothers with a secondary or higher education and who belong to the highest wealth quintile live in households with iodised salt.

Table 11.9 shows the proportion of households with iodised salt according to background characteristics. Overall, salt was tested in 87 percent of the households and two-thirds (66 percent) of the tested households had iodised salt. Although the presence of any iodine is most commonly accepted to define iodised salt, the test kits allow classification as to whether the salt contains at least 15 parts per million (ppm) of iodine, which constitutes the adequate amount of iodisation. Using this criterion, only 4 in 10 of the tested households (39 percent) had adequately iodised salt. Although Ghana is far from the 90 percent USI target, these results show substantial improvements in the percentage of households that use any iodised salt and that use adequately iodised salt from 42 percent and 28 percent, respectively, in the 2003 GDHS to 66 percent and 39 percent, respectively, in the 2014 GDHS.

The percentage of households using any iodised salt is far greater in urban (72 percent) than rural areas (58 percent). Western region has the highest proportion of households using iodised salt (84 percent), while Volta and Eastern regions have the lowest proportions (42 percent each). The proportion of households using iodised salt rises steadily from 54 percent in the poorest households to 84 percent in the wealthiest households.

Table 11.9 Presence of iodised salt in household

Among all households, the percentage with salt tested for iodine content and the percentage with no salt in the household; and among households with salt tested, the percent distribution by level of iodine in salt (parts per million or ppm) and percentage with iodised salt, according to background characteristics, Ghana 2014

Background characteristic	Among all households, the percentage			Among households with tested salt:

11.9 ADULT NUTRITIONAL STATUS

11.9.1 Nutritional Status of Women

The 2014 GDHS collected anthropometric data on height and weight for women age 15-49 who were interviewed in the survey and were eligible for biomarker data collection. These data were used to assess low maternal height and body mass index (BMI). Women who were pregnant and women who had given birth in the two months preceding the survey were excluded from the BMI calculations. For only 1

percent of women, there was no information on height and/or weight and a BMI could not be estimated, and these women were excluded from this analysis.

Maternal height is an outcome of genetics combined with the effects of nutrition during childhood and adolescence. It helps to predict a risk of difficult delivery because small stature is frequently associated with small pelvic size. The risk of low birth weight babies is also higher for short women. The cutoff point—that is, the height below which a woman is considered to be at risk for poor birth outcomes and obstetric complications—is defined as 145 centimeters. Table 11.10.1 shows that 1 percent of Ghanaian women age 15-49 measure below this height.

Information on BMI is also presented in Table 11.10.1. BMI is calculated by dividing weight in kilograms by height in meters squared (kg/m^2). Pregnant women and women who had a birth in the two months preceding the survey were excluded from the calculation of BMI. A BMI cutoff point of 18.5 has been recommended for assessing chronic energy deficiency among nonpregnant women. At the other end of the BMI scale, women are considered overweight if their BMI falls between 25.0 and 29.9 and obese if their BMI is 30.0 or greater.

Overall, 54 percent of Ghanaian women have a BMI in the normal range, 6 percent are thin, and 40 percent are overweight or obese. Five percent of women are classified as mildly thin, and 1 percent are moderately or severely thin. Overweight and obesity seem be of greater concern in Ghana compared with thinness. The mean BMI for women age 15-49 in Ghana is 24.8 kg/m^2. The mean BMI generally increases with age, with the lowest value (21.3 kg/m^2) being observed in the youngest women age 15-19 and the highest value (27.2 kg/m^2) being observed for women age 40-45. The mean BMI is positively associated with women's education and household wealth.

Overall, 25 percent of women in Ghana are overweight, and 15 percent are obese. The proportion of overweight/obese women is positively correlated with women's age; this proportion increases from 9 percent among women age 15-19 to 56 percent for women age 40-49. Urban women are substantially more likely to be overweight/obese than their rural counterparts (49 percent versus 28 percent). Marked regional differences are notable, with women in Greater Accra being more than four times as likely to be overweight/obese as those in Northern (57 percent versus 12 percent). As expected, the proportion of overweight/obese women correlates positively with household wealth: this percentage increases steadily from 13 percent in the lowest wealth quintile to 60 percent in the highest wealth quintile. Similarly, the proportion of overweight/obese women increases with education, affecting 27 percent of women with no education and 49 percent of those with a secondary or higher education.

Table 11.10.1 Nutritional status of women

Among women age 15-49, the percentage with height under 145 cm, mean body mass index (BMI), and the percentage with specific BMI levels, by background characteristics, Ghana 2014

11.9.2 Nutritional Status of Men

For the first time in a Ghana DHS, anthropometric data on height and weight were collected among men age 15-59. These data are useful in BMI calculations, which can be used as a measure of chronic energy deficiency among men (BMI calculations and cutoff points are the same for men and women). In addition, BMI can be used to measure overweight and obesity, risk factors for nutrition-related chronic diseases such as diabetes mellitus and cardiovascular disease.

Table 11.10.2 shows BMI information for Ghanaian men. Overall, 74 percent of men age 15-49 have a BMI in the normal range, 10 percent are thin, and 16 percent are overweight or obese. Men age 15-19 (27 percent) are more likely to be thin than older men. Further, men with a primary education (18 percent) are three times as likely to be thin as men with a secondary or higher education (6 percent).

Overall, the prevalence of overweight/obesity among men is strikingly lower than the prevalence among women (16 percent versus 40 percent). The percentage of men who are overweight/obese is higher in urban than rural areas (23 percent versus 8 percent), and it is highest among men residing in Greater Accra (30 percent). Similar to women, the proportion of overweight/obese men increases with wealth.

Table 11.10.2 Nutritional status of men

Among men age 15-49, mean body mass index (BMI), and the percentage with specific BMI levels, by background characteristics, Ghana 2014

Background characteristic	Mean body mass index (BMI)	Normal	Thin			Overweight/obese			Number of men

11.10 PREVALENCE OF ANAEMIA IN WOMEN

Anaemia is the result of one of the most prevalent micronutrient deficiencies in women. Consequences include impaired health and well- being and increased risk of maternal and neonatal adverse outcomes. The 2014 GDHS collected data on the prevalence of anaemia in women age 15-49 using the same equipment and procedures used to measure anaemia in children. Table 11.11 shows the prevalence of anaemia in women age 15-49 by background characteristics.

Overall, 42 percent of women in Ghana are anaemic, 32 percent are mildly anaemic, 10 percent are moderately anaemic, and less than 1 percent are severely anaemic. Generally, anaemia is less prevalent among women than among children.

Table 11.11 Prevalence of anaemia in women

Percentage of women age 15-49 with anaemia, by background characteristics, Ghana 2014

Background characteristic		Anaemia status by haemoglobin level				Number of women

Note: Prevalence is adjusted for altitude and for smoking status if known using formulas in CDC, 1998. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

The highest prevalence of anaemia is among the youngest women age 15-19 (48 percent), and the prevalence is lowest among women age 30-39 (39 percent). Anaemia prevalence among pregnant women is similar to that among lactating women (45 percent), but slightly higher than the prevalence among women who are neither pregnant nor breastfeeding (41 percent). Place of residence does not make a major difference on the prevalence of anaemia among women. Anaemia prevalence ranges from 36 percent among women in Upper West and Brong Ahafo to 49 percent of women in Volta. Prevalence of any anaemia is lowest among women with a secondary or higher education (40 percent) and among women in the highest two wealth quintiles (37-38 percent).

Trends data indicate that anaemia prevalence among women 15-49 in Ghana increased from 45 percent in 2003 to 59 percent in 2008, and then it decreased to 42 percent in 2014. The prevalence of moderate anaemia shows similar trends, with the most noticeable reduction occurring in the last six years (Figure 11.8).

11.11 MICRONUTRIENT INTAKE AMONG MOTHERS

Adequate micronutrient intake has important benefits for both women and their children. Breastfeeding children benefit from micronutrient supplementation that mothers receive, especially vitamin A. Iron supplementation of women during pregnancy protects the mother and infant against anaemia, which is considered a major cause of perinatal and maternal mortality. As indicated in the previous section, anaemia can also result in a premature or a low birth weight delivery. Finally, iodine deficiency is related to a number of adverse pregnancy outcomes including abortion, foetal brain damage and congenital malformation, stillbirth, and prenatal death.

The 2014 GDHS collected data on consumption of vitamin A and iron-folic acid supplements among women age 15-49 with a child born in the past five years. Also assessed were deworming medication during the last pregnancy and the percentage of women living in households with iodised salt.

Table 11.12 shows that 68 percent of women received vitamin A capsules during the postpartum period. Women in urban areas (73 percent) have a greater likelihood of receiving a postpartum vitamin A than their rural counterparts (64 percent). The coverage of postpartum vitamin A supplementation ranges from 62 percent in Eastern region to 72 percent in Greater Accra, Ashanti, and Upper West regions.

Women with secondary or higher education are most likely to receive Vitamin A supplements within two months of childbirth compared with women with no education (76 percent versus 61 percent). Similarly, postpartum vitamin A supplementation increases with wealth, from 59 percent of women in the lowest wealth quintile to 80 percent of those in the highest quintile.

Table 11.12 also shows the number of days that women took iron tablets or syrup during the pregnancy of their last birth in the past five years. Fifty-nine percent of women took iron tablets daily for 90 or more days during their last pregnancy, 9 percent for 60 to 89 days, and 21 percent for fewer than 60 days. Overall, 8 percent of pregnant women did not take any iron supplements at all.

The proportion of women who took daily iron supplements for 90 or more days during their last pregnancy, which is the recommended dose, is substantially higher in urban than rural areas (67 percent

versus 53 percent). Women in the Upper West region are most likely to take iron supplements daily for 90 or more days (83 percent) and those in the Eastern region are the least likely to do so (32 percent). The proportion of women who took iron supplements daily for 90 or more days is related to education and wealth. Women with a secondary or higher education are more likely to take iron tablets for 90 or more days (73 percent) than women with no education 55 percent). Similarly, women in the highest wealth quintile are notably more likely to take iron tablets for 90 or more days during pregnancy (77 percent) than those in the lowest wealth quintile (50 percent).

Helminthes (intestinal parasites) infections are one of the factors contributing to anaemia among pregnant women. Deworming during pregnancy is a cost-effective intervention against intestinal worms that allows better absorption of nutrients and iron, thus reducing the prevalence of anaemia. Table 11.12 shows that only 4 in 10 women (39 percent) took deworming medication during their last pregnancy. Rural women are more likely to take deworming medication (42 percent) than those living in urban areas (36 percent). There are wide regional variations, with the lowest proportion of women who took deworming tablets during their last pregnancy being in Ashanti (25 percent) and the highest being in Upper East (70 percent). This proportion is higher among women with no education (42 percent) than among those with a secondary or higher education (34 percent). The coverage of deworming supplementation is highest among women in the lowest wealth quintile (43 percent) and lowest among those in the wealthiest households (29 percent).

Iodine deficiency has adverse effects on all population groups, but women of reproductive age are often the most affected. As mentioned, iodine deficiency is related to adverse pregnancy outcomes such as abortion, foetal brain damage and congenital malformation, stillbirth, and perinatal death. As a result, use of iodised salt by women of reproductive age is emphasised. Table 11.12 shows that 63 percent of women with a child born in the five years preceding the survey live in households with iodised salt. Women in urban areas are more likely to live in households that use iodised salt (71 percent) than women in rural areas (58 percent). At the regional level, Western has the highest proportion of women living in households with iodised salt (82 percent), while Volta has the lowest proportion (41 percent). The percentage of women living in households that use iodised salt is positively related to women's educational level and wealth status.

Table 11.12 Micronutrient intake among mothers

Among women age 15-49 with a child born in the past five years, the percentage who received a vitamin A dose in the first two months after the birth of the last child, the percent distribution by number of days they took iron tablets or syrup during the pregnancy of the last child, and the percentage who took deworming medication during the pregnancy of the last child; and among women age 15-49 with a child born in the past five years and who live in households that were tested for iodised salt, the percentage who live in households with iodised salt, by background characteristics, Ghana 2014

[2] Excludes women in households where salt was not tested

MALARIA

> **Key Findings:**
>
> - In Ghana, 68 percent of households own an insecticide-treated net. A higher percentage of households in rural than in urban areas own an insecticide-treated net (78 percent versus 60 percent).
> - The night before the survey, 47 percent of children under age 5 slept under an insecticide-treated net in all households, an increase from 4 percent in 2003 and 39 percent in 2008.
> - Forty-three percent of pregnant women in all households, slept under an insecticide-treated net the night before the survey, an increase from 3 percent in 2003 and 27 percent in 2008.
> - Eighty-five percent of nets in Ghana are free to households.
> - One in six households (17 percent) disposed of a treated net during the past 12 months. The main reason for disposing of the treated nets is that they are torn (83 percent).
> - The most common method of disposal of the treated nets is throwing them into the garbage or refuse dump (66 percent).
> - Ten percent of households reported that they had received indoor residual spraying (IRS) in the past 12 months. IRS is substantially higher in Upper East (79 percent) region, Northern and Upper West regions (37 and 32 percent).
> - Eighty-three percent of women with a live birth in the two years preceding the survey took at least one dose of SP/Fansidar during an antenatal care visit; 68 percent took two or more doses and 39 percent took three or more doses, at least one of which was received during a visit.
> - Eight percent of children age 6-59 months had a low haemoglobin level (less than 8.0 g/dl), indicating possible malarial infection.
> - The prevalence of malaria in children age 6-59 months is 36 percent as measured by RDT and 27 percent as measured by analysis of blood smears via microscopy.

Malaria is one of the leading causes of death in sub-Saharan Africa. Although preventable and curable, the disease remains a public health problem in Ghana. Malaria occurs every year and transmission intensity varies throughout the year. The disease affects all ages but children under 5 and pregnant women are the most vulnerable groups. The malaria burden is felt not only in the health sector but also in other sectors such as social and economic ones.

This chapter presents data that are useful for assessing the implementation of malaria control strategies. These strategies include indoor residual spraying of dwellings with insecticides, increased availability and use of mosquito nets, prophylactic and therapeutic use of antimalarial medicines, and the collection of diagnostic tests (blood sample) from children with fever.

12.1 OWNERSHIP OF MOSQUITO NETS

Use of long-lasting insecticide-treated nets (LLINs) is a form of personal protection that reduces illness, severe disease, and death in endemic regions. LLINs are promoted by WHO and Roll Back Malaria partners as a cost-effective and sustainable method for protection against malaria. LLINs are nets treated in the factory with an insecticide incorporated into the net fabric. The insecticide lasts three to five years, or

at least 20 washes, after which the net should be replaced. With LLINs, therefore, the time-consuming method of retreating old nets is no longer necessary. Promoting LLINs is a primary health intervention designed to reduce malaria transmission in Ghana.

In Ghana, the Ministry of Health (MoH) recommends household use of LLINs as they greatly reduce the cost and the operational difficulties associated with retreatment of nets. Most mosquito nets are provided free of charge by the MoH and the Ghana Health Service (GHS) through several channels, such as mass distribution campaigns and targeted distributions through schools, child welfare clinics, and antenatal clinics. In an effort to make mosquito nets more affordable and accessible, as of 2002, the government of Ghana had waived taxes on the importation of nets into the country, while development partners have contributed by procuring LLINs and supporting their distribution.

For this survey, an insecticide-treated mosquito net (ITN) is a factory-treated net that does not require any further treatment, or a pretreated net obtained in the past 12 months, or a net that has been soaked with insecticide within the past 12 months. LLINs are factory-treated mosquito nets made with netting material that has insecticide incorporated within or bound around the fibres.

All households in the 2014 GDHS were asked whether they owned mosquito nets and, if so, how many. Table 12.1 shows household ownership of nets by type (any mosquito net, ITN, or LLIN) and average number of nets per household, by background characteristics. Overall, 70 percent of households in Ghana own at least one net, regardless of type. Sixty-eight percent of households own at least one net that meets one of the ITN criteria (i.e., a factory-treated net that does not require retreatment, a pretreated net obtained within the previous 12 months, or a net soaked in insecticide at some time within the 12 months prior to the survey). The majority of these ITNs are long-lasting insecticidal nets (64 percent).

Ownership of an ITN differs markedly by residence; 60 percent of urban households own at least one ITN, as compared with 78 percent of rural households. Households in the Greater Accra region are least likely to own an ITN (53 percent), while households in Brong Ahafo are most likely to own one (81 percent). The percentage of households that own at least one ITN decreases substantially with increasing wealth, from 80 percent of households in the lowest quintile to 58 percent of households in the highest quintile. There has been an increase in the household ownership of any type of mosquito net and of any ITN since 2008 from 45 percent to 70 percent and from 42 percent to 68 percent, respectively.

The average number of ITNs per household in Ghana is 1.3.

Although mosquito net ownership is a key indicator of the success of malaria control measures, universal net coverage can be measured by assuming that each net is shared by two people in a household. Table 12.1 shows the percentage of households with at least one mosquito net for every two persons who stayed in the household the night before the interview. Forty-five percent of households in Ghana have at least one ITN for every two persons who stayed in the household the night before the survey. This percentage is highest among rural households (50 percent), households in Brong Ahafo (59 percent), and households in the second wealth quintile (51 percent).

Table 12.1 Household possession of mosquito nets

Percentage of households with at least one mosquito net (treated or untreated), insecticide-treated net (ITN), and long-lasting insecticidal net (LLIN); average number of nets, ITNs, and LLINs per household; and percentage of households with at least one net, ITN, and LLIN per two persons who stayed in the household last night, by background characteristics, Ghana 2014

[1] De facto household members
[2] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN) or (2) a pretreated net obtained within the past 12 months or (3) a net that has been soaked with insecticide within the past 12 months

12.2 ACCESS TO AN INSECTICIDE-TREATED NET

The 2014 GDHS collected data on the proportion of the household population that could sleep under an ITN if each ITN in the household were used by up to two people. This population is referred to as having access to an ITN. Coupled with mosquito net usage, ITN access can provide useful information on the magnitude of the gap between ITN ownership and use (in other words, the population with access to an ITN but not using it). If the difference between these indicators is substantial, the programme may need to focus on behaviour change and how to identify the main drivers of and barriers to ITN use in order to design an appropriate intervention. Such an analysis would help ITN programme managers to determine whether they need to achieve higher ITN coverage, promote ITN use, or both.

Table 12.2 shows the percent distribution of the de facto household population by the number of ITNs owned by the household, according to the number of persons who stayed in the household the night before the survey. One in four households in Ghana (26 percent) have no ITN, one in five have one or three ITNs (21 percent and 20 percent, respectively), and one in four have two ITNs (26 percent).

Nationally, 59 percent of the household population in Ghana has access to an ITN. Access to an ITN fluctuates with household size; it is lowest among households with eight or more persons (48 percent) and highest among households with two or four persons (64 percent each).

[1] Percentage of the de facto household population who could sleep under an ITN if each ITN in the household were used by up to two people

Figure 12.1 shows the percentage of the household population with access to an ITN, by selected background characteristics. A higher percentage of rural than urban households have access to an ITN (64 percent and 54 percent, respectively). By region, this percentage is highest in Volta and Brong Ahafo regions (70 percent each) and lowest in Greater Accra (49 percent). The percentage of the household population with access to an ITN tends to decrease with increasing wealth, although the pattern is not linear.

12.3   USE OF MOSQUITO NETS

Community-level protection against malaria helps reduce the spread of the disease and offers an additional level of protection for those most vulnerable: children under age 5 and pregnant women. This section describes use of mosquito nets among all persons in the household, among children under age 5, and among pregnant women.

12.3.1 Use of Mosquito Nets by Persons in the Household

Mosquito net coverage of the entire population is necessary to accomplish large reductions in the malaria burden. Although vulnerable groups (e.g., children under age 5 and pregnant women) should still be prioritised, the communal benefits of wide-scale ITN use by older children and adults should be promoted and evaluated by national malaria control programmes (Killeen et al. 2007).

Table 12.3 shows that, overall, only 37 percent of the household population slept under a net the night before the survey; 36 percent slept under an ITN, nearly all of which (33 percent) are LLINs. Children under age 5 are most likely to sleep under ITNs (47 percent). The population in rural areas is substantially more likely than urban population to sleep under an ITN (47 percent versus 24 percent). Notable differences are observed by region, with Volta having the highest percentage of household members who slept under an ITN the night before the survey (54 percent) and Greater Accra having the lowest percentage (16 percent). The percentage of the household population who slept under a net tends to decrease with wealth, from 46-50 percent of the population in the lowest two wealth quintiles to 18 percent of the population in the highest wealth quintile.

Forty-four percent of the household population slept either under an ITN the night before the survey or in a dwelling with indoor residual spraying (IRS) during the 12 months preceding the survey.

The proportion of the household population who slept under an ITN the night before the survey or slept in a dwelling that was sprayed during the 12 months preceding the survey is higher among children under age 5 (54 percent) when compared with other age groups, and it is twice as high in rural as in urban areas (58 percent versus 29 percent). The Upper East region has the highest percentage of the household population who slept under an ITN the night before the survey or slept in a dwelling that was sprayed during the 12 months preceding the survey (85 percent), and Greater Accra has the lowest percentage (18 percent).

In households that own at least one ITN, 48 percent of household members slept under an ITN the night before the survey. Those most likely to sleep under an ITN were children under age 5 (59 percent), household members living in rural areas (58 percent), those living in Volta (65 percent), and the population living in the second poorest households (61 percent).

Table 12.3 Use of mosquito nets by persons in the household

Percentage of the de facto household population who slept the night before the survey under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), under a long-lasting insecticidal net (LLIN), and under an ITN or in a dwelling in which the interior walls have been sprayed against mosquitoes (IRS) in the past 12 months; and among the de facto household population in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Ghana 2014

[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.
[2] Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or nongovernmental organisation

Figure 12.2 presents data on ownership and coverage of, access to, and use of ITNs in Ghana. About 7 in 10 households (68 percent) own at least one ITN. However, only 45 percent of households have enough ITNs to cover their entire household population (assuming that one ITN is used by two persons).

Fifty-nine percent of household members have access to an ITN, and 36 percent slept under an ITN the night before the survey. The difference between the percentage of households owning an ITN and the percentage of households with at least one ITN for every two persons who stayed in the household the night before the survey indicates that households in Ghana do not have sufficient number of ITNs to cover the households population. Similarly, the difference between the percentage of household population with access to an ITN within their household and the percentage who slept under an ITN the night before the survey indicates that ITN use is much lower than ITN access among the household population.

Figure 12.2 Ownership of, access to, and use of ITNs

GDHS 2014

12 3.2 Use of Existing Mosquito Nets

Table 12.4 presents data on use of existing ITNs. Overall, 49 percent of ITNs were used by someone in the household the night before the survey, 59 percent in rural areas and 36 percent in urban areas. By region, Northern has the highest proportion of ITN usage (61 percent), while Greater Accra has the lowest proportion (26 percent). Use of existing ITNs decreases steadily with wealth, declining from 65 percent among the poorest households to 27 percent among the wealthiest ones.

[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months

12.3.3 Use of Mosquito Nets by Children under Age 5

Malaria is endemic in all regions of Ghana. Those living in areas of high malaria transmission acquire immunity to the disease over time (Doolan et al. 2009). Acquired immunity is not the same as sterile immunity; that is, acquired immunity does not prevent infection but rather protects against severe disease and death. Age is an important factor in determining levels of acquired immunity to malaria. For about six months following birth, antibodies acquired from the mother during pregnancy protect children born in areas of endemic malaria. This immunity gradually disappears, and children start to develop their own immunity. The pace at which immunity develops depends on the level of exposure to malarial infection; in highly malaria-endemic areas, children are thought to attain a high level of immunity by their fifth birthday. Such children may experience episodes of illness but usually do not suffer from severe, life-threatening malaria. Immunity in areas of low malaria transmission is acquired more slowly. Malaria affects all age groups of the population in Ghana.

Table 12.5 shows the use of mosquito nets by children under age 5. Data show that nearly half of children (48 percent) slept under a mosquito net the night before the survey; 47 percent slept under an ITN (nearly all of which – 43 percent – are LLINs). Additionally, 54 percent of children under age 5 either slept under an ITN the night before the survey or slept in a dwelling sprayed with IRS in the past 12 months. Among households with at least one ITN, 59 percent of children under age 5 slept under an ITN the night before the survey.

The percentage of children under age 5 in all the households who slept under an ITN the night before the survey decreases with their age from 52 percent of children under 12 months to 41 percent of those 48-59 months. This percentage is higher in rural than in urban areas (55 percent versus 36 percent). There are variations by region, with Volta having the highest percentage of children under age 5 who slept under an ITN (66 percent) and Greater Accra region having the lowest percentage (26 percent). The percentage of children under age 5 who slept under an ITN the night before the survey tends to decrease with household wealth.

It is notable that while only one-third of children under age 5 in the Upper East region slept under an ITN the night before the survey (37 percent), when the recent IRS is taken into consideration, the proportion of protected children is the highest in country: 86 percent of children under age 5 in Upper East slept under an ITN the night before the survey or in a dwelling sprayed with IRS in the past year, compared with 26-69 percent of children in the other regions.

Table 12.5 Use of mosquito nets by children

Percentage of children under age 5 who, the night before the survey, slept under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), under a long-lasting insecticidal net (LLIN), and under an ITN or in a dwelling in which the interior walls have been sprayed against mosquitoes (IRS) in the past 12 months; and among children under age 5 fin households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Ghana 2014

Total	47.8	46.6	43.0	53.8	5,801	58.8	4,602

Note: Table is based on children who stayed in the household the night before the interview.
[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.
[2] Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or nongovernmental organisation.

12.3.4 Use of Mosquito Nets by Pregnant Women

In malaria-endemic areas, adults usually acquire some degree of immunity to severe, life-threatening malaria. However, pregnancy leads to suppression of the immune system; thus, pregnant women, especially those in their first pregnancy, have a high risk of malarial infection. Moreover, malaria among pregnant women may be asymptomatic. Malaria during pregnancy is a major contributor to low birth weight, maternal anaemia, infant mortality, spontaneous abortion, and stillbirth. Pregnant women can reduce the risk of these adverse effects of malaria by sleeping under insecticide-treated mosquito nets.

Table 12.6 shows the use of mosquito nets by pregnant women by background characteristics. Overall, 45 percent of pregnant women age 15-49 slept under any net the night before the survey, 43 percent slept under an ITN (the majority of which—39 percent—were LLINs). In addition, half of pregnant women either slept under an ITN the night before the survey or slept in a dwelling that had been sprayed in the past 12 months. Among households with at least one ITN, more than half of pregnant women (54 percent) slept under an ITN the night before the survey.

ITN use by pregnant women in all households is higher in rural than in urban areas (55 percent versus 31 percent). ITN use is lowest among pregnant women living in Greater Accra (18 percent), among women with a secondary or higher education (30 percent), and among those in the highest two wealth quintiles (25-28 percent).

Similar to children under age 5, although only one-third of pregnant women in the Upper East region slept under an ITN the night before the survey (34 percent), the proportion of pregnant women who are protected is the highest in country. During the night before the survey, 83 percent of pregnant women in Upper East slept under an ITN or in a dwelling sprayed with IRS in the past 12 months, compared with 19-69 percent of pregnant women in the other regions.

Table 12.6 Use of mosquito nets by pregnant women

Percentages of pregnant women age 15-49 who, the night before the survey, slept under a mosquito net (treated or untreated), under an insecticide-treated net (ITN), under a long-lasting insecticidal net (LLIN), and under an ITN or in a dwelling in which the interior walls have been sprayed against mosquitoes (IRS) in the past 12 months; and among pregnant women age 15-49 in households with at least one ITN, the percentage who slept under an ITN the night before the survey, by background characteristics, Ghana 2014

Note: Table is based on women who stayed in the household the night before the interview. Figures in parentheses are based on 25-49 unweighted cases.
[1] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.
[2] Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or nongovernmental organisation.

12.3.5 Trends in Use of Mosquito Nets by Children under Age 5 and Pregnant Women

Figure 12.3 shows that the proportion of children under age 5, in all households, who slept under an ITN the night before the survey, has increased steadily and substantially in the last decade from 4 percent in 2003, to 39 percent in 2008, and further to 47 percent in 2014. Similarly, among pregnant women in all the households, the percentage who slept under an ITN the night before the survey has increased from 3 percent in 2003, to 27 percent in 2008, and to 43 percent in 2014.

12.3.6 Source and Cost of Nets

Since Ghana's introduction to the Roll Back Malaria initiative in 1998, the mosquito nets have been provided by different public and private sources, during a continuous distribution process or through mass distribution campaigns. According to the National Malarial Control Programme (NMCP), most nets in the country are distributed free of charge (NMCP 2013). To complement net distribution points in the public sector, a private sector E-coupon program was piloted in the Eastern region with the overall objective of stimulating retail markets and offering consumers a choice of product. Marketing strategies created demand and targeted both retailers and consumers. E-coupon issuing points were established close to participating retailers where consumers redeemed their coupons for a discounted net (USAID 2014). E-coupons worth 50 percent of the retail purchase price of a net which was about 17-18 Ghana cedis[1] (GHS) depending on type were issued at participating private clinics, workplaces, pharmacies and other retailers.

The 2014 GDHS household respondents were asked about the source of the mosquito nets in their households and their cost. Table 12.7 shows that 81 percent of the nets in Ghana come from the public sector, while only 2 percent come from the private sector. The data further show that most nets (85 percent) are acquired for free; only one in seven nets (15 percent) is purchased. Rural households are more likely to acquire nets for free when compared with urban households (87 percent versus 83 percent). By region, the percentage of households acquiring free nets is remarkably high in the Upper East and Northern

---

[1] Ghanaian cedi (GHS) = approximately 0.32 US Dollars (as of December 2014)

regions (94-95 percent) and falls below 80 percent in Greater Accra (79 percent). This percentage decreases with increasing wealth, from 89 percent of the poorest households to 80 percent of the wealthiest ones.

The mean cost of the purchased nets is 7.2 Ghana cedis.

Table 12.7 Source and cost of nets

Percent distribution of mosquito nets by source and mean cost of mosquito nets in Ghana cedis, according to background characteristics, Ghana, 2014

12.3.7 Disposal of Nets

A substantial number of mosquito nets are being distributed in Ghana as part of the country's efforts towards universal net coverage. Disposal of the used or expired nets, especially insecticide-treated nets, introduces waste into the environment. Concerns arise over the potential environmental and human health harm associated with the disposal of used, treated nets and their non-biodegradable packaging materials The NMCP, in consultation with the Malaria Vector Control Oversight Committee and Ghana's Environmental Protection Agency, has considered recycling the used nets and their packaging materials. The process is supported by various manufacturers and donor agencies. The ITN and LLIN manufacturers are especially receptive to the idea of more environmentally friendly practices, including recycling the used nets and switching to biodegradable packaging materials.

The 2014 GDHS household respondents were asked if they disposed of any treated nets in the past 12 months and, if so, what was the mode of disposal, length of use prior to net disposal, and main reason for the disposal. Tables 12.8 and 12.9 present the findings. Overall, one in six households (17 percent) disposed of a treated net during the past 12 months. This proportion is highest among households in rural areas (21 percent), in the Northern region (24 percent), and in the lowest wealth quintile (25 percent).

Table 12.8 Household disposal of mosquito nets

Percentage of households with at least one mosquito net (treated or untreated) that disposed of any treated nets during the past 12 months, by background characteristics, Ghana 2014

Background characteristic	Percentage that disposed of at least one treated net in the past 12 months	Number of households with at least one mosquito net
Residence		
Urban	11.9	3,983
Rural	21.3	4,253
Region		
Western	18.5	878

Fourth	12.7	1,714
Highest	11.1	1,579
Total	16.8	8,236

Table 12.9 shows that the most common method of disposal of the treated nets is by throwing them into the garbage or refuse dump (66 percent). In addition, 17 percent of households burned their nets and 14 percent used them for another purpose. Urban households are more likely than rural households to throw their used nets into the garbage or refuse dumps (70 percent versus 63 percent), while rural households are more likely than urban households to reuse their nets for another purpose (18 percent versus 6 percent).

Table 12.9 Mosquito net disposal

Percent distribution of households that disposed of any treated net in the 12 months preceding the survey, by method of disposal, length of use prior to disposal, and main reason for disposal of the last disposed treated net, according to residence, Ghana 2014

Method of disposal/Length of use prior to disposal/Main reason for disposal	Residence		Total
	Urban	Rural	
Method of disposal of last treated net disposed			
Burned	19.2	16.4	17.4
Buried	1.8	1.3	1.5
Garbage or refuse dump	70.2	63.0	65.5
Reused for other purpose	6.4	17.6	13.7

Torn	77.8	85.6	82.9
Could not repel mosquitos anymore	10.5	7.3	8.4
Got a new one	9.3	6.1	7.2
Other/Don't know	2.0	0.9	1.3
Total	100.0	100.0	100.0
Number of households that disposed of a treated net in the past 12 months	476	908	1,383

Note: Totals may not add up to 100 percent because households with missing information are not shown separately.

Fifty-five percent of households disposed of their treated nets after using them for less than two years. According to WHO, the current generation of LLINs lasts for three to five years (WHO/Global Malaria Programme 2007). In Ghana, 40 percent of households disposed of their treated nets after using them for two to four years. Data show that the main reason for disposing of the treated nets is that they are torn (83 percent), indicating that nets in the country are not lasting as long as expected.

12.4 INDOOR RESIDUAL SPRAYING

Indoor residual spraying (IRS), a key component of malaria prevention, is part of the integrated vector management strategy in Ghana. IRS has a significant impact on the mosquito population and, therefore, can lead to rapid reductions in malaria transmission and subsequent mortality. IRS involves spraying of the interior walls with insecticide with the goal of killing mosquitoes when they rest on the sprayed walls. In addition to reducing the mosquito population and, in turn, human-vector contact, IRS decreases the population of other insects of public health importance, thus reducing overall morbidity and saving costs. IRS is implemented as a vector control strategy in selected districts based on the burden and technical feasibility. The IRS programme targets 63 districts in six of the ten regions in Ghana. However, as of 2013, it had covered only 33 districts in the targeted six regions. AngloGold Ashanti, a private mining company, and the USAID-President's Malaria Initiative (PMI) have been the main implementers of IRS.

To obtain information on the prevalence of indoor residual spraying, all households interviewed in the 2014 GDHS survey were asked whether the interior walls of their dwelling had been sprayed to protect against mosquitoes during the 12-month period before the survey and, if so, who had sprayed the dwelling. Table 12.10 shows that only 10 percent of households had been sprayed in the 12 months preceding the survey. There is a difference in IRS by residence, with rural households being three times as likely as urban households to have been sprayed in the past 12 months (15 percent versus 5 percent). Regionally, only 2 percent or less of households in Greater Accra, Volta, Eastern, and Brong Ahafo had their dwelling sprayed, as compared with 79 percent of households in Upper East, 37 percent of households in Northern, and 32 percent of households in Upper West, all malaria-endemic regions. Households in the lowest wealth quintile (29 percent) are much more likely to have been sprayed when compared with households in the other wealth quintiles (5-9 percent).

The combination of IRS and use of an ITN offers the greatest protection against malaria. Overall, 71 percent of households are protected by owning at least one ITN and/or by having received IRS in the past 12 months. Variations by residence, region, and wealth are similar to the ones observed for IRS in the past 12 months. Rural households are more likely than urban households to have at least one ITN and/or to have been sprayed against mosquitoes in the preceding 12 months (58 percent versus 44 percent). This proportion is highest among households in Upper East (93 percent) and those in the bottom wealth quintile (86 percent).

ITNs must be available in sufficient quantities for use by household members. Only half of the households in Ghana have at least one ITN for every two persons and/or have been sprayed in the past 12 months.

Fifty-three percent of households had their dwelling sprayed by government workers or programmes, 18 percent were sprayed by nongovernmental organisations, and 15 percent were sprayed by private sector companies (data not shown).

Table 12.10 Indoor residual spraying against mosquitoes

Percentage of households in which someone has come into the dwelling to spray the interior walls against mosquitoes (IRS) in the past 12 months, the percentage of households with at least one ITN and/or IRS in the past 12 months, and the percentage of households with at least one ITN for every two persons and/or IRS in the past 12 months, by background characteristics, Ghana 2014

Background characteristic	Percentage of households with IRS[1] in the past 12 months	Percentage of households with at least one ITN[2] and/or IRS in the past 12 months	Percentage of households with at least one ITN[2] for every two persons and/or IRS in the past 12 months	Number of households

[1] Indoor residual spraying (IRS) is limited to spraying conducted by a government, private, or nongovernmental organisation.
[2] An insecticide-treated net (ITN) is (1) a factory-treated net that does not require any further treatment (LLIN), or (2) a pretreated net obtained within the past 12 months, or (3) a net that has been soaked with insecticide within the past 12 months.

12.5 USE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA DURING PREGNANCY

In areas of high malaria transmission, by the time an individual reaches adulthood, he or she has acquired immunity that protects against severe disease. However, pregnant women—especially those pregnant for the first time—frequently regain their susceptibility to malaria. Although malaria in pregnant women may not manifest itself as either febrile illness or severe disease, it is frequently the cause of mild to severe anaemia. In addition, malaria during pregnancy can interfere with the maternal-foetal exchange that occurs at the placenta, leading to the delivery of low birth weight infants, miscarriage, foetal death, or still birth.

Policies on malaria during pregnancy are well articulated in Ghana. Intermittent preventive treatment of malaria during pregnancy (IPTp) is provided as part of the antenatal care (ANC) package. The recommended medicine, sulphadoxine-pyrimethamine (SP), is administered free to pregnant women as a directly observed therapy in both public and private ANC delivery points across the country (MoH 2014).

Women in the 2014 GDHS who had a live birth in the two years preceding the survey were asked whether they took any antimalarial medications during the pregnancy leading to their most recent birth and, if so, which types of medication. Women were also asked whether the medicines they took were received during a prenatal care visit. It should be noted that obtaining information about medicines can be difficult because some respondents may not know or remember the name or the type of medicines that they received.

Table 12.11 shows that 83 percent of women with a live birth in the two years preceding the survey reported taking at least one dose of SP/Fansidar during an ANC visit; 68 percent reported taking two or more doses of SP/Fansidar, and 39 percent reported taking three or more doses of SP/Fansidar, at

least one of which was received during an ANC visit. A higher proportion of women in urban than in rural areas received three or more doses of SP/Fansidar, at least one of which was received during an ANC visit (42 percent and 36 percent, respectively). This proportion is highest among women in the Brong Ahafo region (52 percent) and lowest among women in Upper East (31 percent). When compared with other subgroups, women with a secondary or higher education and those in the wealthiest households (51 percent each) are the most likely to have received three or more doses of SP/Fansidar, with at least one dose received during an ANC visit.

Table 12.11 Use of intermittent preventive treatment (IPTp) by women during pregnancy

Percentage of women age 15-49 with a live birth in the two years preceding the survey who, during the pregnancy preceding the last birth, received any SP/Fansidar during an ANC visit, and who took at least two doses of SP/Fansidar and received at least one dose during an ANC visit, and who took at least three doses of SP/Fansidar and received one dose during an ANC visit, by background characteristics, Ghana 2014

Background characteristic	Percentage who received any SP/Fansidar during an ANC visit	Percentage who took 2+ doses of SP/Fansidar and received at least one during ANC visit	Percentage who took 3+ doses of SP/Fansidar and received at least one during ANC visit	Number of women with a live birth in the two years preceding the survey

The 2014 GDHS interviewers asked women with a live birth in the two years preceding the survey to show the ANC cards for the most recent pregnancy that resulted in a live birth. The interviewers recorded the number of doses of SP/Fansidar given to women during their last pregnancy as documented on the ANC cards that were seen. To compare the number of doses of SP/Fansidar received based on the mother's self-reporting with the number of doses recorded on the ANC cards, self-reported IPTp was recalculated on the subsample of women with a live birth in the two years preceding the survey *with an ANC card seen* for the most recent pregnancy. Among this subsample of women, 86 percent reported taking one dose of SP/Fansidar during an ANC visit, compared with 83 percent as recorded on the ANC cards; 69 percent reported taking two or more doses at least one of which was received during an ANC visit, compared with 70 percent as recorded on the ANC cards; and 40 percent reported taking three or more doses of SP/Fansidar, at least one of which was received during an ANC visit, compared with 41 percent as recorded on the ANC cards (data not shown). These percentages are similar to those shown in Table 12.11 that are based on self-reported IPTp among all women with a live birth in the two years preceding the survey.

Data from the 2014 GDHS shows marked improvement in IPTp coverage since the 2008 GDHS, when the MoH and the Ghana National Malaria Control Programme recommended that pregnant women receive at least two doses of SP/Fansidar during pregnancy as IPTp against malaria. In the 2008 GDHS,

only 44 percent of women reported receiving two or more doses, at least one of which was during an ANC visit compared with 68 percent in 2014 GDHS.

12.6 PREVALENCE, DIAGNOSIS, AND PROMPT TREATMENT OF CHILDREN WITH FEVER

In 2010, the Ghana policy of presumptive diagnosis was revised to require testing for malaria before any treatment. This led to the introduction of the rapid diagnostic test (RDT) kits. The diagnosis of malaria in Ghana is based on detection of parasites in the blood using malaria rapid diagnostic tests (MRDT), which are widely available in all public and private health facilities, as well as using microscopy in all public and private hospitals and clinics. Prompt and effective treatment of malaria treatment is essential to prevent the disease from progressing to a severe stage, thus becoming more dangerous. Fever is a major manifestation of malaria in young children, although it also accompanies other illnesses. In malaria endemic areas, it is important that children experiencing fever receive prompt testing for malaria parasites, either by rapid diagnostic test or by microscopy to confirm the disease before any malaria medicine is administered.

Guided by the WHO criteria and recommendations, artemisinin-based combination therapy (ACT) remains the medicine of choice for treatment of uncomplicated malaria in Ghana. In 2007, the anti-malaria drug policy was reviewed by the MoH and the GHS to include artemether–lumefantrine (AL) and dihidroartemisinin–piperaquine (DHAP) as additional options to artesunate–amodiaquine. These changes have since addressed the identified lapses, such as adverse reactions of varying degrees of severity reported across the country. AL and DHAP, however, target mostly individuals who are hypersensitive to artes-unate–amodiaquine (MoH 2014).

As a primary manifestation of malaria, fever occurs year round but malaria is most prevalent during the rainy season. Therefore, temporal factors must be taken into consideration when interpreting the occurrence of fever as an indicator of malaria prevalence. Malaria case management, one of the most fundamental strategic areas of malaria control, is the identification, diagnosis, and prompt treatment of all malaria cases with appropriate and effective antimalarial medicines. As almost all treatment of malarial fevers occurs at home, caregivers are often trained in providing prompt and effective management to prevent malaria from becoming severe, thus preventing malaria-related morbidity and mortality.

In the 2014 GDHS, mothers were asked if their children under age 5 had experienced an episode of fever in the two weeks preceding the survey and, if so, whether treatment and advice were sought. Information was also collected on the type and timing of the treatment given. Table 12.12 shows the percentage of children under age 5 who had a fever in the two weeks preceding the survey and, among those with a fever, (1) the percentage for whom advice or treatment was sought from a health facility, provider, or pharmacy; (2) the percentage who had a drop of blood taken from a finger or heel (presumably for a malaria test); (3) the percentage who took artemisinin-based combination therapy or any antimalarial medicine; and (4) the percentage who took medicines on the same or next day.

Fourteen percent of children under age 5 had fever in the two weeks preceding the survey. The prevalence of fever is highest among children age 12-35 months (17 percent). It is slightly higher among male than female children (15 percent versus 13 percent), and among children living in rural than in urban areas (15 percent versus 12 percent). Furthermore, the percentage of children with fever in the two weeks before the survey is highest in Upper West (25 percent), among children whose mothers have no education (16 percent), and among those in the lowest two wealth quintiles (16-17 percent).

Among children who had fever in the last two weeks, advice or treatment was sought for 77 percent, and 34 percent had blood taken from a finger or heel for testing. Thirty-eight percent of children who had a fever took ACT, and 26 percent took ACT the same or the next day. Thirty-four percent of children with a fever took antimalarial medicines the same or next day.

There are slight variations in the percentage of children with fever for whom advice or treatment was sought by background characteristics. The percentage of children for whom advice or treatment was sought for their fever is highest in the 12-23 month age group (82 percent), among female children (80 percent), among those living in the Western region (91 percent), among children of mothers with a secondary or higher education (84 percent), and among those in the fourth wealth quintile (83 percent).

Table 12.12 Prevalence, diagnosis, and prompt treatment of children with fever

Percentage of children under age 5 with fever in the two weeks preceding the survey; and among children under age 5 with fever, the percentage for whom advice or treatment was sought, the percentage who had blood taken from a finger or heel, the percentage who took any artemisinin-based combination therapy (ACT), the percentage who took ACT the same or next day following the onset of fever, the percentage who took antimalarial medicines, and the percentage who took antimalarial medicines the same or next day following the onset of fever, by background characteristics, Ghana 2014

[1] Excludes market and traditional practitioner

Among children under age 5 with fever in the past two weeks who took antimalarial medicines, 78 percent took ACT, 9 percent took SP/Fansidar, 7 percent took quinine, 3 percent took chloroquine, 2 percent took artemisinin, and 4 percent took other antimalarial medicines (data not shown due to the small numbers of children who had a fever and who took antimalarials).

Table 12.13 shows the sources of advice or treatment for children with fever in the two weeks preceding the survey. The public sector is the principal source for advice or treatment (60 percent). For about 4 in 10 children with fever (38 percent), advice or treatment was sought from the private sector. The government health centres (30 percent) and government hospitals (24 percent) are the main public sources, while the pharmacy/chemical/drug stores (27 percent) are the main private sector sources of advice or treatment.

Table 12.13 Source of advice or treatment for children with fever

Percentage of children under age five with fever in the two weeks preceding the survey for whom advice or treatment was sought from specific sources; and among children under age five with fever in the two weeks preceding the survey for whom advice or treatment was sought, the percentage for whom advice or treatment was sought from specific sources, by background characteristics, Ghana 2014

12.7   PREVALENCE OF LOW HAEMOGLOBIN IN CHILDREN

The 2014 GHDS also assessed the prevalence of anaemia among children age 6-59 months (see also Chapter 11 in this report). Poor dietary intake of iron is only one of numerous causes of anaemia; malaria infection can also result in a person becoming anaemic. A haemoglobin concentration of less than 8.0 g/dl is considered low and may indicate an individual has malaria (Korenromp et al. 2004).

Overall, 8 percent of children age 6-59 months have a haemoglobin level less than 8.0 g/dl (Table 12.14). Children 12-17 months (17 percent), those living in rural areas (12 percent) and in the Northern and Upper West regions (18 percent and 17 percent, respectively), and children in the lowest wealth quintile (16 percent) are the most likely to have low haemoglobin levels.

Table 12.14 Haemoglobin <8.0 g/dl in children

Notes: Table is based on children who stayed in the household the night before the interview. Prevalence of anaemia is based on haemoglobin levels and is adjusted for altitude using CDC formulas (CDC, 1998). Haemoglobin is measured in grams per decilitre (g/dl). An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] Includes children whose mothers are deceased
[2] For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

12.8 PREVALENCE OF MALARIA IN CHILDREN

Another objective of the 2014 GHDS was to test children age 6-59 months for malaria. Field health technicians collected capillary blood samples from children in this age group in half of the households surveyed. Testing for malaria was done in the field using a rapid diagnostic test (RDT). The SD Bioline Malaria Ag P.f/Pan is a high-sensitivity and high-specificity test that detects malaria antigens from capillary blood samples. Thick blood smear samples were prepared and sent to the National Public Health and Reference Laboratory to be examined microscopically to determine the presence of malaria parasites.

Overall, 97 percent of the 2,781 eligible children age 6-59 months had their blood tested for malaria with RDT and microscopy.

Table 12.15 shows that the prevalence of malaria in children age 6-59 months is 36 percent as measured by RDT and 27 percent as measured by analysis of blood smears via microscopy. A possible reason for the higher malaria prevalence based on RDT than on microscopy is that the antigens may still be present in the child's blood after the parasites have disappeared. Malaria prevalence based on microscopy results is much higher among children living in rural than in urban areas (38 percent versus 14 percent). By region, it ranges from 11 percent in Greater Accra to 40 percent in Northern. Malaria prevalence according to microscopy decreases from 42 percent among children living in the poorest households to 8 percent among those living in the richest households.

A comparison of the 2014 GDHS results with those from the 2011 Ghana MICS survey shows that the prevalence of malaria among children as measured by RDT[2] has decreased from 48 percent to 36 percent. The prevalence as measured by analysis of blood smears via microscopy has not changed since 2011 (28 percent in 2011 and 27 percent in 2014) (GSS 2011).

Table 12.15 Prevalence of malaria in children

Percentage of de facto children age 6-59 months classified as having malaria, according to RDT and according to microscopy, by background characteristics, Ghana 2014

12.9 EXPOSURE TO MESSAGES ON MALARIA

Behavioural communication change (BCC) strengthens all strategic components of malaria control and prevention programmes by supporting interventions like case management improvement, integrated vector management, and programme management. The MoH and the NMCP have adopted BCC as a key strategy to ensure that the Ghanaian people are exposed to messages that increase knowledge and promote positive behavioural changes. These lead to malaria prevention and proper management, such as use of LLINs and seeking proper diagnosis and prompt and effective treatment within 24 hours of diagnosis. BCC involves dissemination of malaria prevention and treatment messages through various media sources, such as TV, radio, newspapers and magazines, posters, leaflets and brochures, and through health workers and community volunteers.

---

[2] The 2011 Ghana MICS used the Care Start Combo rapid diagnostic test.

The 2014 GDHS incorporated a series of questions for the household respondents on recent exposure (in the past six months) to malaria messages through various sources. Findings are shown in Table 12.16.

Table 12.16 Exposure to messages on malaria by media source

Percentage of household questionnaire respondents who saw or heard a message on malaria through various sources in the past 6 months, according to background characteristics, Ghana, 2014

Total	63.6	79.4	12.0	27.2	7.6	32.4	12.9	4.6	7.9	11,835

Not surprisingly, large proportions of household respondents said they had heard or seen malaria messages on the radio (79 percent) and TV (64 percent) in the past six months. Twenty-seven percent of respondents had read or seen malaria messages on a poster, 12 percent in a newspaper or magazine, and 8 percent on leaflets or brochures. Data further show that 32 percent of household respondents had heard malaria messages from a health worker and 13 percent had heard them from a community volunteer. This is a decline from the 2008 GDHS figures of 42 percent and 22 percent, respectively.

Exposure to malaria messages through the various media sources is more common in urban than in urban areas. Regionally, Greater Accra has the highest percentage of respondents who are exposed to malaria messages through the TV (84 percent), newspaper/magazine (20 percent), or posters (39 percent). Ashanti has the highest exposure to malaria messages through the radio (86 percent) and via leaflets/brochures (11 percent). There are also large differences by wealth quintile; exposure to malaria messages through the various media increases steadily with increasing wealth.

Rural respondents are more likely than their urban counterparts to have received malaria messages from a health worker (38 percent and 28 percent, respectively) or from a community volunteer (18 percent and 9 percent, respectively). Exposure to malaria messages through a health worker or a community volunteer is lowest in Greater Accra (19 percent and 5 percent, respectively) and highest in Upper West (48 percent and 52 percent, respectively). These percentages are also highest among the poorest respondents and decrease notably with wealth.

Overall, 8 percent of the household respondents have not had any exposure to malaria messages through the various specified sources in the past 6 months. This percentage is highest among respondents living in rural areas (10 percent) and those living in Volta (17 percent), and among respondents in the lowest two wealth quintiles (13 percent each).

12.9.1 Exposure to Specific Messages on Malaria

Mass media messages on malaria in Ghana are many and they vary. Some of these messages can be misleading or confusing. This is especially true for radio commercials about local herbal preparations that supposedly treat malaria or for commercials about mosquito coils that are claimed to repel or kill mosquitoes and protect against malaria.

To gauge exposure to accurate malaria messages that are approved by the Ministry of Health and the Ghana Health Service, household respondents were asked about exposure to these specific messages in the past 6 months. Table 12.17 shows that 93 percent of household respondents had heard messages that families should sleep under an ITN to protect them from malaria, especially pregnant women and children under age 5. About three-quarters of the household respondents had heard each of the messages that: treatment should be sought from health facilities within 24 hours of the onset of childhood fever, especially for children under age 5; that GHS recommends ACT as medicine for malaria; that the full course of ACT should be completed; and that pregnant women should attend antenatal clinics and take three doses of SP/Fansidar during pregnancy to prevent malaria. Exposure to any of the specified messages on malaria is higher among respondents in urban than in rural areas, and it increases steadily with wealth.

Only 4 percent of respondents had not heard any of the specified malaria messages. This percentage is highest among respondents in Volta (11 percent) and those in the poorest households (8 percent).

Table 12.17 Exposure to specific messages on malaria

Percentage of household questionnaire respondents who heard or saw a specific messages on malaria in the past 6 months, according to background characteristics, Ghana, 2014

Background characteristic	Specific messages on malaria in the past 6 months					No exposure to any of the specified malaria messages	Number of household respondents
	Treatment should be sought from health facilities within 24hours of onset of fever, especially for children under age 5	The Ghana Health Service recommends ACT as medicine for malaria	The full course of the malaria medicine, ACT, should be completed	Pregnant women should attend ANC and take 3 doses of SP/Fansidar during pregnancy to prevent malaria	Families should sleep under insecticide treated nets (ITNs) to protect them from malaria, especially pregnant women and children under age 5

ACT = Artemisinin-based combination therapy

Contrary to the moderate level of ITN usage, 93 percent of household respondents have heard messages that families should sleep under an ITN to protect them from mosquito bites and hence malaria. Seventy-six percent have heard that pregnant women should attend antenatal clinics and take three doses of SP/Fansidar for IPT.

More than three-quarters of household respondents (76 percent) have heard that the GHS recommends ACTs for treatment of malaria; and the same proportion (76 percent) are aware that the full treatment course of ACTs should be completed. Seventy-four percent have heard that treatment should be sought from health facilities within 24 hours of the onset of childhood fever for children under 5 years.

The proportion of respondents who have heard the messages about malaria in Table 12.18 appears to increase with household wealth and it is generally higher among urban respondents, although the degree of urban-rural difference varies from the message to message. The Central, Ashanti, Northern and Western regions are more likely to have heard messages on the recommended treatment for malaria and the need to seek prompt care. Respondents in the Upper East region are least likely to have heard messages on the recommended treatment for malaria, and the need to seek prompt care, and to complete the full course of treatment. More than half of respondents in the Upper East region (66 percent) heard that pregnant women should go to the antenatal clinic for IPT, compared with 84 percent of respondents in the Central region.

The 2014 GDHS results on the malaria messages heard or seen by household respondents, point to an interesting behavioural pattern if viewed against the results of ITN use, IPT uptake, and the management of fever in children under age 5. These findings reflect a gap between the level of exposure of the Ghanaian population to messages about malaria and the actual malaria-related practices in the household. For instance, even though 93 percent of household respondents have heard or seen messages that "families should sleep under insecticide treated nets to protect them from malaria, especially pregnant women and children under age 5", only 47 percent of children under age 5 and 43 percent of pregnant women in all the surveyed households had actually slept under an ITN the night before the survey (Tables 12.5 and 12.6).

HIV/AIDS-RELATED KNOWLEDGE, ATTITUDES, AND BEHAVIOUR

13

> **Key Findings:**
>
> - Knowledge of HIV and AIDS in Ghana is universal; almost all women and men age 15-49 have heard of AIDS.
> - Overall, for respondents age 15-49, women are less likely than men to have comprehensive knowledge about HIV and AIDS (18 percent of women versus 30 percent of men).
> - Women (61 percent) are more aware than men (52 percent) that HIV can be transmitted through breastfeeding and that this risk can be reduced by taking special drugs.
> - Eight percent of women and 14 percent of men age 15-49 have expressed accepting attitudes towards people living with HIV (PLHIV).
> - Fifty-three percent of women and 58 percent of men age 15-49 agree that children age 12-14 years should be taught about using a condom to avoid AIDS.
> - Fifty-two percent of women and 78 percent of men age 15-49 have never been tested for HIV.
> - Male circumcision is almost universal in Ghana.
> - Forty-seven percent of women and 32 percent of men age 18-24 reported having sexual intercourse before age 18.

Acquired immune deficiency syndrome (AIDS) is caused by the human immunodeficiency virus (HIV). This virus weakens the immune system and makes the body susceptible to and unable to recover from other opportunistic diseases. To estimate the distribution of new infections and to identify those populations at highest risk for HIV infection in Ghana, a Modes of Transmission (MOT) study applying the UNAIDS model was conducted in 2014 and its findings indicate that the majority of infections (73 percent) occur among stable heterosexual couples and persons involved in casual heterosexual sex together with their regular partners (GAC 2014).

Ghana's national response to HIV has made significant progress towards achieving Universal Access to HIV services through the implementation of robust and a vibrant National HIV and AIDS Strategic Framework (NSF). NSF 1 covered the period 2001-2005, and NSF II covered the period 2006-2010. In line with efforts to continue and sustain this progress, The Ghana AIDS Commission (GAC), in collaboration with key partners and stakeholders, developed and is implementing a National Strategic Plan on HIV and AIDS 2011-2015 (NSP 2011-2015) which is directing the implementation of the national HIV and AIDS response (GAC 2011). Ghana is in the fifth year of implementing this strategy which takes into account the unique challenges that it faces in addressing the HIV epidemic. Although Ghana is among countries with a low HIV prevalence, efforts for responding to the epidemic need to be sustained and scaled up to maintain and even lower the prevalence. It is for this reason that the NSP set ambitious targets which aim at achieving universal access as well as the Millennium Development Goals (MDGs). Overall, the focus of the 2011-2015 strategy is to reduce by half the new HIV infections by the end of its fifth year of implementation; with a virtual elimination of mother to child transmission of HIV, as well as sustaining and scaling up the proportion of people living with HIV (PLHIV) who are on treatment, leveraging treatment as a prevention strategy (GAC 2011).

The National HIV Prevalence and AIDS Estimates Reports show the national HIV response is making modest progress. In 2012, about 236,000 people were living with HIV. The number of new HIV infections reduced from 12,077 in 2011 to 7,991 in 2012; adults contributed 89 percent, children

contributed 11 percent, and young people 15-24 years of age contributed 28 percent (2,236 of 7,991) of new HIV infections in 2012. The proportion of new HIV infections occurring in the 15-24 age group in 2012 is notably lower than the 37 percent (4,438 of 12,077) reported in 2011. The National AIDS Control Programme (NACP) data indicate that 70 percent of HIV positive pregnant women received ARV prophylaxis to prevent mother to child transmission of HIV against the NSP target of 70 percent in 2012 and 61 percent of eligible PLHIV are receiving ART against the NSP target of 80 percent in 2013. Stock outs of HIV test kits and ARVs have significantly hampered optimal access to HIV counseling and testing (HCT), PMTCT, and ART services (GHS 2014).

To address these problems GAC has re-strategised and refocused by filling and bridging relevant gaps in the national response to ensure HIV interventions are evidence based and results oriented to enable effective HIV service delivery. The thrust and direction of this current strategy of investing in evidence-based, high-impact HIV and AIDS priority interventions when followed through in association with critical social and programmatic enablers would ensure synergy with development sectors be maintained and strengthened. The key high impact program interventions areas in this new direction are targeted behaviour change communication (BCC) interventions, condom promotion and distribution, interventions for key populations, PMTCT programmes, and treatment and care. The critical social and programmatic enablers include political commitment and advocacy; community mobilisation, and stigma reduction, community capacity enhancement, program communication, management and incentives, research and innovations. Synergies with development sector intervention areas include social protection and poverty reduction, education, legal reforms, gender equality, and sexual and gender based violence, health and community systems strengthening, and employer practices (GAC 2013).

Despite the gains made by the national response, HIV and AIDS-related stigma and discrimination is still a pervasive problem, and PLHIV in Ghana, as elsewhere, face stigma and discrimination in a variety of contexts and places, such as the household, community, workplace, and health care settings. A PLHIV Stigma Index study conducted in 2014 shows PLHIV avoided all the forms of social exclusion and other forms of discrimination through non-disclosure of their HIV status to individuals and groups outside the health care delivery system. Furthermore, the results indicate there were also higher levels of stigma against HIV-positive members of key populations than other PLHIV (GAC 2014).

The 2014 GDHS questionnaire asked a series of questions that asks about respondents' knowledge of HIV prevention, misconceptions about HIV transmission, and knowledge of mother to child transmission (MTCT) if HIV and means to prevent it. The survey also included questions relating to HIV testing and counselling (HTC) such as where to test and whether respondent had ever been tested for HIV and received results. Respondents were also asked their experiences with regards to symptoms of sexually transmitted infections (STIs) and their health seeking behaviours relating to STIs. The last set of questions in this module sought the opinions of both women and men on a wife's justification in refusing her husband sex. The chapter also highlights HIV and AIDS knowledge and patterns of sexual behaviour among young people, since young adults are more likely to be in the process of establishing patterns of sexual behaviours and hence are the primary target of many prevention strategies.

13.1 HIV/AIDS KNOWLEDGE, TRANSMISSION, AND PREVENTION METHODS

Women and men respondents in the 2014 GDHS were asked whether they have heard of an illness called AIDS. Respondents who reported having heard about the illness AIDS were asked other questions about how to avoid the disease. These series of questions also sought information on respondents' knowledge regarding use of condoms to prevent STI.

13.1.1 Knowledge of AIDS

Table 13.1 shows the percentage distribution of women and men age 15-49 who have heard of AIDS by background characteristics in Ghana. According to the findings presented in this table, knowledge of AIDS is almost universal among respondents age 15-49 (98 and 99 percent for women and

men respectively). This is consistent with the 2003 and 2008 GDHS findings. Knowledge of AIDS does not vary much by most background characteristics, except by region, education, and wealth quintile. As can be seen from Table 13.1, awareness of AIDS is lowest among women and men in the Northern region (same as in the 2008 GDHS). Awareness of AIDS increases with level of education. Nearly all women and men with at least middle/JSS/JHS education have heard about AIDS, compared with 92 percent of women and 95 percent of men who have no education. Similarly, women and men in the higher wealth quintiles are more likely to have heard of AIDS than those in the lowest wealth quintile.

13.1.2 Knowledge of HIV Prevention methods

In Ghana, HIV is transmitted among adults primarily through heterosexual contact between an infected partner and a non-infected partner. Consequently, HIV prevention programmes focus messages and efforts on promoting the following specific behaviours: use of condoms, limiting the number of sexual partners to one uninfected partner or staying faithful to one uninfected sexual partner and, for young people, delaying their first sexual intercourse (sexual debut).

To assess whether interventions have effectively communicated messages relating to condom use, reduction of sexual partners and delayed sexual debut, respondents were asked if people can reduce their chances of getting the virus that causes AIDS by using a condom every time they have sex, by having just one uninfected sexual partner who has no other sexual partners, and by not having sexual intercourse at all. Table 13.2 shows that 77 percent of women and 86 percent of men age 15-49 know that consistent use of condoms is a means of preventing the spread of HIV. Eighty-four percent of women and 92 percent of men know that limiting sexual intercourse to one uninfected partner can reduce the chances of contracting HIV. The proportion who said that people can reduce the chances of getting the AIDS virus by using condoms and limiting sex to one uninfected partner is higher among men (82 percent) than among women (70 percent). Among women, Central region (83 percent) has the highest knowledge of HIV prevention methods whereas Northern region has the lowest (45 percent). The proportion of women and men with knowledge of HIV prevention methods increases with increasing education. For example, knowledge of both prevention methods rises from 56 percent among women with no education to 79 percent among those with a secondary or higher education. Similarly, knowledge of HIV prevention methods increases with increasing wealth. These findings indicate that HIV prevention education could be strengthened further in certain groups of individuals, particularly those who are young, those who have little or no education, and those in the lowest wealth quintile. On the whole HIV prevention knowledge has increased compared with the results of the 2008 GDHS.

Table 13.2 Knowledge of HIV prevention methods

Percentage of women and men age 15-49 who, in response to prompted questions, say that people can reduce the risk of getting the AIDS virus by using condoms every time they have sexual intercourse, and by having one sex partner who is not infected and has no other partners, by background characteristics, Ghana 2014

[2] Partner who has no other partners

13.1.3 Comprehensive Knowledge about HIV/AIDS

In addition to knowing effective ways to avoid contracting HIV, it is useful to be able to identify incorrect beliefs about HIV transmission. Common misconceptions about HIV and AIDS include the following: a healthy-looking person cannot have HIV, HIV can be transmitted by mosquito bites, HIV can be transmitted by supernatural means, and a person can become infected by sharing food with a person who has HIV. Respondents were asked about these misconceptions and whether they have heard about anti-retroviral drugs. The findings are presented in Tables 13.3.1 and 13.3.2 for women and men, respectively.

Eighty-two percent of women and 85 percent of men age 15-49 agreed that a healthy-looking person can have HIV. In terms of different misconceptions about HIV transmission, 60 percent of women and 63 percent of men said that HIV cannot be transmitted by mosquito bites; 35 of percent of women and 52 percent of men know that HIV cannot be transmitted by supernatural means; and 68 percent of women and 71 percent of men said that a person cannot become infected by sharing food with a person who has AIDS.

The questions asked in the 2014 GDHS allow an assessment of comprehensive knowledge about HIV and AIDS among respondents. Comprehensive knowledge is defined as knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting HIV, knowing that a healthy-looking person can have HIV, and rejecting the two most common local misconceptions about HIV transmission (that HIV can be transmitted by mosquito bites and that HIV can be transmitted by supernatural means).

Twenty-three percent of women and 34 percent of men indicated that a healthy looking person can have HIV and rejected the two most common misconceptions. Overall, women are less likely than men to have comprehensive knowledge about AIDS (18 percent of women versus 30 percent of men age 15-49). Comprehensive knowledge about HIV and AIDS has decreased somewhat since the 2008 GDHS, which reported that 25 percent of women and 37 percent of men age 15-49 had comprehensive knowledge.

Women age 20-24, those who have never married, and women living in urban areas are more likely than other women to have comprehensive knowledge of HIV and AIDS. Among men, those age 25-29 and men who have never been married but have ever had sex are most likely to have comprehensive knowledge of HIV and AIDS. By region, comprehensive knowledge is highest among women and men in the Central and Greater Accra regions and lowest among women in the Upper West region and among men in the Volta region. Comprehensive knowledge of HIV and AIDS increases steadily with increasing education and wealth quintile for both women and men.

Antiretroviral therapy (ART) is used to treat HIV. These drugs do not kill or cure HIV; however, they can postpone or prevent progression of HIV infection to AIDS. In the 2014 GDHS both women and men respondents were asked if they have heard about special antiretroviral drugs, or ARVs, such as nevirapine, zidovudine and lamivudine that people living with HIV can get from a doctor or a nurse to help them live longer. Overall, 63 percent of women and 76 percent of men age 15-49 said they have heard about antiretroviral medicine. However, less than half of women in Western, Volta and Northern regions have heard about ARV drugs. Only 25 percent of men in the Northern region have heard about ARVs, compared with 93 percent of men in Greater Accra. The likelihood of have heard about ARVs increases with level of education and wealth quintile for both men and women.

Table 13.3.1 Comprehensive knowledge about AIDS: Women

Percentage of women age 15-49 who say that a healthy-looking person can have the AIDS virus and who, in response to prompted questions, correctly reject local misconceptions about transmission or prevention of the AIDS virus, the percentage with a comprehensive knowledge about AIDS, and the percentage who have heard of antiretroviral medications, by background characteristics, Ghana 2014

Background characteristic	Percentage of women who say that:				Percentage who say that a healthy looking person can have the AIDS virus and who reject the two most common local miscon-ceptions[1]	Percentage with a compre-hensive knowledge about AIDS[2]	Heard about antiretroviral medicine	Number of women

[1] Two most common local misconceptions: that the AIDS virus can be transmitted by mosquito bites and that the AIDS virus can be transmitted by supernatural means
[2] Comprehensive knowledge means knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention.

13.2 KNOWLEDGE ABOUT MOTHER-TO-CHILD TRANSMISSION

Ghana is working seriously towards zero new infections. In view of this, the country recognises the need to implement effective and efficient interventions towards achieving this goal. In this regard, the country in collaboration with its partners are rolling out prevention of mother to child transmission of HIV services by encouraging pregnant women to know their HIV sero-status in order to reduce the risk of

transmission of the virus from mother to child. This intervention is a key component of prevention of mother-to-child transmission (PMTCT) service delivery and acts as the entry point of care for mothers.

In the survey, to assess PMTCT knowledge, respondents were asked whether HIV can be transmitted from a mother to a child through breastfeeding and whether a mother with HIV can reduce the risk of transmission to her baby by taking certain medications during pregnancy.

Table 13.4 shows that in the 2014 GDHS, over three-quarters of respondents age 15-49, are aware that HIV can be transmitted through breastfeeding (78 percent of women and 76 percent of men). Sixty-four percent of women and 61 percent of men know that the risk of mother-to-child transmission (MTCT) can be reduced by taking special medication. Overall, 61 percent of women and 52 percent of men age 15-49 are aware that HIV can be transmitted through breastfeeding and that this risk can be reduced by taking special medication.

Table 13.4 Knowledge of prevention of mother-to-child transmission of HIV

Percentage of women and men age 15-49 who know that HIV can be transmitted from mother to child by breastfeeding and that the risk of mother to child transmission (MTCT) of HIV can be reduced by the mother taking special drugs during pregnancy, by background characteristics, Ghana 2014

na = Not applicable

Knowledge of PMTCT is highest among women age 25-29 and those who are formerly married. Among men, PMTCT knowledge increases with age and it is highest for men 40-49, those who have never married but ever had sex, and men who are divorced, separated or living with a partner. There is little difference in the level of PMTCT knowledge by women's current pregnancy status. PMTCT knowledge is higher among women and men in urban areas than among women and men in rural areas, with the difference being more pronounced for men. PMTCT knowledge varies widely by region; it is lowest among women and men in the Northern region (40 percent and 27 percent, respectively) and highest among women and men in Western region (68 percent and 62 percent, respectively). Among both women and men, awareness that HIV can be transmitted through breastfeeding and that the risk of MTCT can be reduced by taking special medication during pregnancy increases with increasing education and, in general, increasing wealth quintile.

13.3 ATTITUDES TOWARDS PEOPLE LIVING WITH HIV/AIDS

Widespread stigma and discrimination against people living with HIV/AIDS (PLHIV) can adversely affect people's well-being and constitutes a barrier to the uptake of HIV services such as testing for HIV (HTC) as well as seeking out and adhering to antiretroviral therapy (ART). There are over 235,982 persons living with HIV in Ghana (NACP 2013), and stigmatising and discriminating against them can jeopardise or endanger disclosure, confidentiality, and self-esteem.

Ghana has campaigned against stigma and discrimination against people living with HIV using the concept of 'Heart to Heart' Ambassadors whereby PLHIV who have disclosed their status publically use mass media to educate the general population on stigmatisation and discrimination (GAC 2011). Ghana places considerable emphasis on this strategy because reduction in stigma and discrimination is an important indicator of the success of programmes targeting HIV and AIDS prevention and control.

In the 2014 GDHS, respondents who had heard of AIDS were asked a number of questions to assess the level of stigma associated with HIV and AIDS. Respondents were asked about their willingness to care for a family member with AIDS in their own home, whether they would buy fresh vegetables from a shopkeeper or vendor who has HIV, and whether they agree that a female teacher who has HIV but is not sick should be allowed to continue teaching. More men (54 percent) than women (43 percent) would not want to keep it a secret that a family member has HIV. Tables 13.5.1 and 13.5.2 present the results for women and men, respectively.

Seventy percent of women and 74 percent of men age 15-49 said that they would be willing to care for a relative with AIDS in their home, and 30 percent of women and 36 percent of men agreed they would buy fresh vegetables from shopkeepers who had HIV. Slightly more than half of women (54 percent) and 6 in 10 men (63 percent) agree that a female teacher who has HIV but is not sick should be allowed to continue teaching.

Overall, only 8 percent of women and 14 percent of men age 15-49 expressed accepting attitudes on all four indicators of stigma associated with HIV/AIDS. These results are fairly similar to those in the 2003 GDHS, but slightly lower than those in the 2008 GHDS. This low level of acceptance is a concern for programme implementers. Among women, Greater Accra region has the highest percentage expressing accepting attitudes whilst Northern region has the lowest. Among men, accepting attitudes are most common in Northern region, and least common in Central and Brong Ahafo regions.

The proportion of women and men who express accepting attitudes on all four indicators is higher in urban areas than in rural areas, and increases with level of education and wealth quintile.

Table 13.5.1 Accepting attitudes towards those living with HIV/AIDS: Women

Among women age 15-49 who have heard of AIDS, percentage expressing specific accepting attitudes towards people with HIV/AIDS, by background characteristics, Ghana 2014

| Background characteristic | Percentage of women who: | | | | Percentage expressing acceptance attitudes on all four indicators | Number of women who have heard of AIDS |
	Are willing to care for a family member with AIDS in the respondent's home	Would buy fresh vegetables from shopkeeper who has the AIDS virus	Say that a female teacher who has the AIDS virus but is not sick should be allowed to continue teaching	Would not want to keep secret that a family member got infected with the AIDS virus

13.4 ATTITUDES TOWARDS NEGOTIATING SAFER SEXUAL RELATIONS WITH HUSBANDS

Knowledge about HIV transmission and ways to prevent it is of little use if women feel powerless to negotiate safer sexual practices and men do not understand the implication of unsafe sexual practices on both their lives and the lives of their partners. The high level of sexual transmission of HIV among heterosexual adults makes negotiating safe sex indispensable for women, especially in a marital context in which women's status may be compromised by societal norms and expectations. In an effort to assess the ability of women to negotiate safer sex with a spouse who has sex with other women (who may have STIs), women and men were asked if they thought that a wife is justified in refusing to have sexual intercourse with her husband or asking that he uses condoms, if she knows he has an STI.

Table 13.6 shows that 74 percent of women and 79 percent of men age 15-49 believe that a wife is justified in refusing to have sexual intercourse with her husband if she knows he has sex with other

women. In addition, 91 percent of women and 95 percent of men believe that a woman has a right to ask her husband to use a condom if she knows that he has an STI.

The data show relatively small differences by background characteristics of the respondents. In terms of regional variation, women in the Upper East (81 percent), Greater Accra (80 percent), and Upper West (79 percent) regions are most supportive of a woman refusing to have sexual intercourse with her husband if she knows he has sex with other women. On requesting her husband to use a condom if she knows he has an STI, women in the Greater Accra (96 percent), Ashanti (93 percent), and Volta (92 percent) regions are most supportive. In terms of regional variation among men, those in Central (90 percent), Greater Accra and Brong Ahafo regions (85 percent each) are most supportive of a woman refusing to have sexual intercourse with her husband if she knows he has sex with other women. Respondents with more education and those in the highest quintile are slightly more supportive of women negotiating safer sex with their husbands.

Table 13.6 Attitudes towards negotiating safer sexual relations with husband

Percentage of women and men age 15-49 who believe that a woman is justified in refusing to have sexual intercourse with her husband if she knows that he has sexual intercourse with other women, and percentage who believe that a woman is justified in asking that they use a condom if she knows that her husband has a sexually transmitted infection (STI), by background characteristics, Ghana 2014

Background characteristic	Women			Men		
	Woman justified in:			Woman justified in:		
	Refusing to have sexual intercourse with her husband if she knows he has sex with other women	Asking that they use a condom if she knows that her husband has an STI	Number of women	Refusing to have sexual intercourse with her husband if she knows he has sex with other women	Asking that they use a condom if she knows that her husband has an STI	Number of men

Programme planners and implementers focusing on HIV/AIDS and sexually transmitted infections should take advantage of the relatively high level of acceptance of women negotiating safer sex with their husbands. This high degree of acceptance affords the opportunity to expand and strengthen messages and interventions that promote preventive practices (e.g., use of male and female condoms) and empower women to take ownership of their sexual health.

13.5 ATTITUDES TOWARDS CONDOM EDUCATION FOR YOUNG PEOPLE

Condom use is one of the most effective and efficient strategies for combating the spread of HIV. The social acceptability of condoms is key to determining the success of condoms in preventing sexual transmission of HIV and other STIs, as well as preventing unintended pregnancy. However, educating young people about condoms is sometimes considered controversial; some oppose educating young people about condoms because they think it promotes early sexual experimentation; others favour teaching only abstinence until marriage. To determine attitudes towards condom education, respondents were asked whether they agree that children age 12-14 should be taught about using a condom to avoid getting HIV. Because the focus is on adults' opinions, results are tabulated for respondents age 18-49. Table 13.7 shows that 53 percent of women and 58 percent of men age 18-49 support teaching children age 12-14 about condoms. Women age 25-29 (57 percent) and men age 20-24 (64 percent of men) are most likely to support education of children on condom use, while women and men age 30-49 are the least likely to do so (51 percent of women and 55-56 percent of men).

Urban women are more likely than rural women to agree on teaching children age 12-14 about condom use to avoid HIV (57 percent and 48 percent, respectively). The urban-rural difference is small for men. By region, agreement on teaching children age 12-14 about the use of condoms ranges from 37 percent of women in Ashanti and 47 percent of men in Upper East to 66 percent of women in Greater Accra and 67 percent of men in Eastern. The proportion of respondents who support teaching children age 12-14 about condom use increases with level of education and wealth quintile. For instance, 67 percent of women with a secondary or higher education agree on instructing children 12-14 years about condoms compared with 41 percent of women with no education. Similarly, 63 percent of men with a secondary or higher education, compared with 45 percent of men with no education, agree that youth should be taught about using condoms to avoid HIV.

13.6 HIGHER-RISK SEX

Given that most HIV infections in Ghana are contracted through heterosexual contact, information on sexual behaviour is important in designing, implementing and monitoring interventions to control and manage the spread of HIV. The 2014 GDHS included questions on respondents' number of sexual partners over the 12 months preceding the survey; from this data, the mean number of lifetime sexual partners was computed. In addition, information was collected on women's and men's use of condoms during their most recent sexual intercourse. These questions are sensitive and it is recognised that some respondents may have been reluctant to provide information on recent sexual behaviour. Potentially risky sexual activities relate to men and women having multiple sexual partners and not using condoms.

Tables 13.8.1 and 13.8.2 present information on women and men who have ever had intercourse regarding the number of sexual partners they had during the 12 months before the survey and the estimated number of lifetime sexual partners. For those reporting more than one sexual partner in the past 12 months, information is presented on whether they used a condom during their most recent intercourse. The results of the survey show that women age 15-49 are much less likely than their male counterparts to have reported having multiple sexual partners in the past 12 months (1 percent versus 14 percent). These results are similar to those obtained in the 2008 GDHS, in which 1 percent of women and 11 percent of men reported two or more sexual partners in the past two weeks.

As expected, women in the age group 20-24, women who have never married, and those who are divorced, separated or widowed are somewhat more likely to have two or more sexual partners in the past 12 months when compared with other women. However, variations by background characteristics among women are minimal.

Men who are married or have ever married are most likely to have multiple sexual partners. Men in rural areas are somewhat more likely to report having two or more sexual partners. Men who live in Central region are the most likely to have had multiple sexual partners in the past 12 months. Percentage of men with multiple sexual partners is highest among those with no education (16 percent) and those with a secondary or higher education (15 percent).

The survey also assessed condom use at last sex among women and men with multiple partners in the 12 months preceding the survey. Overall, 11 percent of women and 19 percent of men age 15-49 with multiple sexual partners in the past 12 months used a condom at last sex. Due to small numbers of women with multiple sexual partners, differences by background characteristics cannot be assessed. Among men with multiple partners, those age 20-24 (35 percent), men who have never been married (43 percent), men living in urban areas (24 percent), men in Upper West (31 percent), those with a secondary or higher education (31 percent), and men in the highest wealth quintile (33 percent) are more likely than other men to report using a condom during their last sexual intercourse. The smaller proportions of women with multiple partners compared with men may accurately reflect the Ghanaian context, but is also likely to reflect a bias from some women being shy about reporting behaviour that may not be generally accepted.

Among respondents who ever had sexual intercourse, the average number of lifetime sexual partners is 2.3 for women and 7.3 for men. The 2014 GDHS findings for women (2.3 lifetime sexual partners) are similar to those reported in the 2008 GDHS (2.0 lifetime sexual partners). However, lifetime sexual partners for men increased from 5.3 in the 2008 GDHS to 7.3 in the 2014 GDHS.

There are significant variations in the number of lifetime partners by background characteristics of men. As expected, the number of lifetime sexual partners is smaller for younger men and larger for older men (2.9 for men age 15-19 compared with 9.2 for men age 40-49). Divorced, separated, and widowed men have more partners than never-married men (10.4 and 5.1 sexual partners, respectively). There are notable differences by region, from an average of 2.6 lifetime sexual partners among men in Upper West region to 9.6 in Western region. The mean number of lifetime sexual partners is highest among men with middle/JSS/JHS education and tends to increase with wealth quintile.

Table 13.8.1 Multiple sexual partners: Women

Among all women age 15-49, the percentage who had sexual intercourse with more than one sexual partner in the past 12 months; among those having more than one partner in the past 12 months, the percentage reporting that a condom was used at past intercourse; and the mean number of sexual partners during their lifetime for women who ever had sexual intercourse, by background characteristics, Ghana 2014

13.7 POINT PREVALENCE AND CUMULATIVE PREVALENCE OF CONCURRENT SEXUAL PARTNERS

The point prevalence and cumulative prevalence of concurrent sexual partners are new concepts that were incorporated for the first time in the 2014 GDHS. The point prevalence of concurrent sexual partners is defined as the percentage of respondents who had two (or more) sexual partners concurrently at the point in time six months before the survey. The cumulative prevalence of concurrent sexual partners is defined as the percentage of respondents who had two (or more) sexual partners concurrently at any time during the 12 months preceding the survey. Table 13.9 shows the point prevalence and cumulative prevalence of concurrent sexual partners among all respondents. It also shows the percentage of

respondents who had concurrent sexual partners among those who had multiple sexual partners during the 12 months before the survey.

Among Ghanaian women age 15-49, the point prevalence and the cumulative prevalence are less than 1 percent. For women who had multiple partners during the 12 months before the survey, 44 percent had concurrent sexual partners.

Among Ghanaian men in the same age group, the point prevalence is 6 percent and the cumulative prevalence is 12 percent. Men age 50-59 have a point prevalence of 13 percent and a cumulative prevalence of 15 percent. By marital status, cumulative prevalence of concurrent sexual partners is lowest among never-married men (5 percent) and highest among men who are currently married or living together (18 percent). Among men who had multiple partners during the 12 months before the survey, 84 percent had concurrent sexual partners.

Table 13.9 Point prevalence and cumulative prevalence of concurrent sexual partners

Percentage of all women and men age 15-49 who had concurrent sexual partners 6 months before the survey (point prevalence[1]), and percentage of all women and all men age 15-49 who had any concurrent sexual partners during the 12 months before the survey (cumulative prevalence[2]), and among women and men age 15-49 who had multiple sexual partners during the 12 months before the survey, percentage who had concurrent sexual partners, by background characteristics, Ghana 2014

| Background characteristic | Among all respondents: | | | Among all respondents who had multiple partners during the 12 months before the survey: | |

Note: Two sexual partners are considered to be concurrent if the date of the most recent sexual intercourse with the earlier partner is after the date of the first sexual intercourse with the later partner. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] The percentage of respondents who had two (or more) sexual partners that were concurrent at the point in time 6 months preceding the survey
[2] The percentage of respondents who had two (or more) sexual partners that were concurrent anytime during the 12 months preceding the survey

13.8 PAID SEX

The act of paying for sex introduces an uneven basis for negotiating safer sexual practices. Condom use is an important way to mitigate the risk of HIV transmission with higher-risk sexual partners such as commercial sex workers. Table 13.10 shows the percentage of men age 15-49 who paid for sexual intercourse in the past 12 months by background characteristics.

Only 6 percent of men age 15-49 reported ever paying for sex; 3 percent reported paying for sex during the 12 months preceding the survey. Men who are divorced, separated, or widowed (11 percent), and those living in the Western region (12 percent) are more likely than other men to have paid for sexual intercourse. Other variations by background characteristics are minimal.

Among men who paid for sex in the past 12 months, 42 percent reported using a condom at last paid sexual intercourse (data not shown).

Table 13.10 Payment for sexual intercourse and condom use at last paid sexual intercourse

13.9 COVERAGE OF HIV TESTING SERVICES

Expanding knowledge of HIV status is an important goal of the national HIV response. In the case of persons who are HIV negative, knowledge of their HIV status helps in making specific decisions that will reduce the risk of becoming HIV positive and enable them to remain HIV free. For those who are HIV positive, knowledge of their HIV status allows them to live an affirming life, protecting their sexual partners, accessing care and treatment, and planning for the future. To assess awareness and coverage of prior HIV testing behaviour, respondents were asked if they knew where to get an HIV test and whether they had ever been tested for HIV. If they said they had been tested for HIV, respondents were asked if they had received the results of their last test. Tables 13.11.1 and 13.11.2 present information on prior testing among women and men, respectively.

Table 13.11.1 shows that 79 percent of women age 15-49 know a place where they can get an HIV test. By age group, women age 15-19 (61 percent) are least likely while women age 25-29 (86 percent) are most likely to know where to obtain an HIV test. Knowledge of a place to obtain an HIV test is higher among urban than rural women, and increases from 63 percent among women with no education to 94 percent among those with a secondary or higher education. Percentage who know where to get an HIV test ranges from 52 percent of women in Northern to 92 percent of those in Greater Accra. This percentage increases substantially with wealth.

More than four in ten women age 15-49 in Ghana (43 percent) have ever been tested for HIV and received their results, and 6 percent have been tested but did not receive the test results. The percentage ever tested and who received the test results is lowest among women age 15-19 (11 percent) and highest among those age 25-39 (58 percent). Women who are married or living together (53 percent), those who reside in urban areas (50 percent), women with a secondary or higher education (56 percent), and those in the highest wealth quintile (58 percent) are most likely to have ever been tested for HIV and to have received their results. Only 6 percent of women age 15-49 were tested for HIV but did not receive the test results.

More than half of women age 15-49 (52 percent) have never been tested for HIV. Only 13 percent of women have been tested for HIV in the past 12 months and received results of their last test.

Table 13.11.2 shows that 80 percent of men know where to get an HIV test. Variations by background characteristics are similar to those observed for women. One in five men age 15-49 (20 percent) have been tested for HIV and received their test results. Coverage of HIV testing is highest among those age 30-39 and those who are currently divorced, separated or widowed (29 percent each). Men in urban areas (26 percent) are much more likely than those in rural areas (14 percent) to have ever been tested for HIV and received their results. By region, this percentage ranges from 13 percent each in Brong Ahafo and Northern regions to 29 percent in Greater Accra. The percentage of men who have been tested for HIV generally increases with level of education and wealth quintile. For example, 9 percent of men with no education have been tested for HIV and received their results, compared with 36 percent of men with a secondary or higher education.

Two percent of men have been tested for HIV but did not receive their results. Seventy-eight percent of men have never received an HIV test. Only 6 percent of men have been tested for HIV in the past 12 months and received their results.

Coverage of HIV testing, although still low, has shown a substantial increase over the years. In the 2014 GDHS, 49 percent of women and 22 percent of men have ever been tested for HIV compared with 21 percent of women and 14 percent of men in the 2008 GDHS.

Table 13.11.1 Coverage of prior HIV testing: Women

Percentage of women age 15-49 who know where to get an HIV test, percent distribution of women age 15-49 by testing status and by whether they received the results of the last test, the percentage of women ever tested, and the percentage of women age 15-49 who were tested in the past 12 months and received the results of the last test, according to background characteristics, Ghana 2014

Background characteristic	Percentage who know where to get an HIV test	Percent distribution of women by testing status and by whether they received the results of the last test				Percentage ever tested	Percentage who have been tested for HIV in the past 12 months and received the results of the last test	Number of women

13.10 HIV TESTING DURING PREGNANCY

In Ghana, encouraging pregnant women to know their HIV sero-status in order to reduce the risk of transmission of the virus from mother to child is a key component of Prevention of Mother-To-Child Transmission (PMTCT) service delivery. It also serves as the entry point of care for HIV-positive mothers and is a key prevention intervention being provided at all PMTCT centres across the country.

Table 13.12 presents information on HIV screening during pregnancy among women who gave birth in the two years preceding the survey. Sixty-six percent of women who gave birth during the two years preceding the survey received HIV counselling during antenatal care (ANC) visits (i.e., someone talked with the respondent about all three of the following topics: (1) babies getting HIV from their mother, (2) preventing contracting HIV, and (3) getting tested for HIV). About half of women were tested

for HIV and received the test results and post-test counselling (49 percent), and an additional 12 percent were tested for HIV and received the results but did not receive post-test counselling. Further, 10 percent of women were tested for HIV during an antenatal care visit but did not receive their test results.

Table 13.12 Pregnant women counselled and tested for HIV

Among all women age 15-49 who gave birth in the two years preceding the survey, the percentage who received HIV pretest counselling, the percentage who received an HIV test during antenatal care for their most recent birth by whether they received their results and post-test counselling, and percentage who received an HIV test at the time during ANC or labour for their most recent birth by whether they received their test results, according to background characteristics, Ghana 2014

Background characteristic	Percentage who received counselling on HIV during antenatal care[1]	Percentage who were tested for HIV during antenatal care and who:			Percentage who received counselling on HIV and an HIV test during ANC, and the results	Percentage who had an HIV test during ANC or labour and who:[2]		Number of women who gave birth in the past two years[3]
		Received results and:						
		Received post-test counselling	Did not receive post-test counselling	Did not receive results		Received results	Did not receive results

Total 15-49	66.0	49.1	11.5	10.3	52.6	61.0	10.6	2,264

[1] In this context, "pretest counselling" means that someone talked with the respondent about all three of the following topics: 1) babies getting the AIDS virus from their mother, 2) preventing contracting the virus, and 3) getting tested for the virus
[2] Women are asked whether they received an HIV test during labour only if they were not tested for HIV during ANC
[3] Denominator for percentages includes women who did not receive antenatal care for their last birth in the past two years

Fifty-three percent of women who gave birth in the two years preceding the survey received counselling on HIV, an HIV test during ANC, and the test results. Women age 30-39 (60 percent) and those who are married or living together (54 percent) are more likely than other women to have been counselled and tested for HIV during ANC and to have received the test results. This percentage increases with increasing level of education and wealth quintile. For example, 37 percent of women with no education have been counselled and tested for HIV during ANC and received the results, compared with 74 percent of women with a secondary or higher education. The proportion of women who have been counselled and tested for HIV during ANC increases from 54 percent of women in the lowest wealth quintile to 85 percent of those in the highest quintile.

Sixty-one percent of women had an HIV test either during antenatal care or during labour for their most recent birth and received the results; an additional 11 percent were tested during antenatal care or labour but did not receive the results.

13.11 MALE CIRCUMCISION

Circumcision is widely practiced in Ghana for religious, social, and health purposes. As a result, children are circumcised a few days after birth, except for most royal lineages. Male circumcision has been associated with a lower risk of HIV transmission from women to men (Williams et al. 2006; WHO and UNAIDS 2007). To examine the practice of circumcision at the national level, men interviewed in the 2014 GDHS were asked whether they had been circumcised. The results are presented in Table 13.13.

Data show that male circumcision is almost universal in Ghana, with almost all men being circumcised (96 percent). The practice occurs in all age groups and in both urban and rural areas; however, there are a few variations according to region, ethnicity, education, and wealth quintile. Men in Upper West (72 percent) and those of Gurma ethnicity (70 percent) are the least likely to be circumcised.

Note: Total includes 2 men for whom information on religion is 'Other' or 'Don't know'.

13.12 SELF-REPORTING OF SEXUALLY TRANSMITTED INFECTIONS

Sexually transmitted infections (STIs) are closely linked with HIV because they share similar risk factors. Moreover, STIs can increase the likelihood of contracting HIV. In the 2014 GDHS, respondents who had ever had sexual intercourse were asked whether they had a sexually transmitted infection or symptoms of an STI (a bad-smelling, abnormal discharge from the vagina or penis or a genital sore or ulcer) in the 12 months preceding the survey.

The results presented in Table 13.14 indicate that 25 percent of women and 10 percent of men age 15-49 had an STI or symptoms of an STI in the past 12 months. Respondents in the younger age groups are more likely to report having had an STI or STI symptoms than older age groups. Never-married women and men are more likely to report an STI or symptoms of an STI than other women and men, with the difference being more pronounced among women (35 percent of never-married women compared with 21 percent of currently married and formerly married women). Among men, those in union are least likely to have an STI or symptoms of an STI (8 percent). Women in urban areas and men in rural areas are more likely than their counterparts to report having had an STI or symptoms of an STI.

Table 13.14 Self-reported prevalence of sexually transmitted infections (STIs) and STIs symptoms

Among women and men age 15-49 who ever had sexual intercourse, the percentage who reported having an STI and/or symptoms of an STI in the past 12 months, by background characteristics, Ghana 2014

	Women					Men				
	Percentage of women who reported having in the past 12 months:				Number of women who ever had sexual inter-course	Percentage of men who reported having in the past 12 months:				Number of men who ever had sexual inter-course

na = Not applicable

Over 30 percent of women in the Brong Ahafo, Northern and Volta regions, compared with 12 percent and 14 percent, respectively, of women in Upper East and Upper West. Men in the Upper East and Eastern regions (18 percent and 17 percent, respectively) are more likely to report STI symptoms than men in other regions. There is a positive association between having an STI or symptoms of an STI and level of education among women. The pattern is not seen among men; for example, 11 percent of men with primary or middle/JSS/JHS education reported having had an STI or STI-related symptoms in the past 12 months compared with 7 percent of men with a secondary or higher education and 9 percent of men with no education.

Figure 13.1 shows that the majority of women and men who had an STI or STI symptoms sought advice or treatment from a clinic, hospital, private doctor, or other health professional (61 percent and 58 percent, respectively). Twenty-seven percent of women and 25 percent of men did not seek any treatment when they had an STI or STI symptoms, compared with 40 percent of women and 29 percent of men in 2008.

Figure 13.1 Women and men seeking treatment for STIs
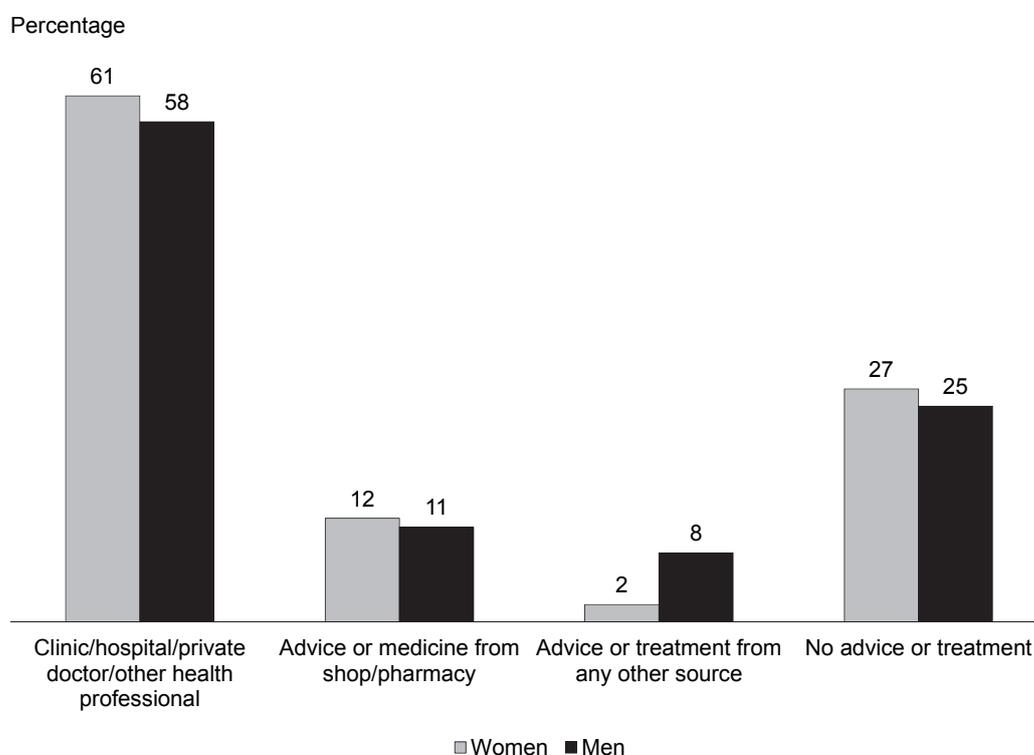

GDHS 2014

13.13 INJECTIONS

Injection practices in a health care setting that are not in line with proper infection prevention procedures can contribute to the transmission of blood-borne pathogens. To measure the potential risk of transmission of HIV associated with medical injections, 2014 GDHS respondents were asked whether they had received any injections from a health worker in the 12 months preceding the survey and, if so, whether their last injection was administered with a syringe from a new, unopened package. It should be noted that self-administered medical injections (e.g., insulin injections for diabetes) were not included in the analysis.

Table 13.15 shows the reported prevalence of injections and of safe injection practices. Thirty-two percent of women and 23 percent of men age 15-49 reported receiving a medical injection from a health worker during the 12 months preceding the survey.

The percentage of women who received medical injections is highest among those age 25-29 (39 percent). This percentage is higher among urban than rural women (34 percent versus 29 percent). By region, the proportion of women who received a medical injection in the past 12 months ranges from a high of 36 percent, each, in Ashanti and Brong Ahafo to a low of 23 percent in Northern.

Among men, there are slight variations by age. By region, the percentage who received a medical injection in the past 12 months ranges from 29 percent in the Western region to 15 percent in the Northern region.

Table 13.15 Prevalence of medical injections

Percentage of women and men age 15-49 who received at least one medical injection in the past 12 months, the average number of medical injections per person in the past 12 months, and among those who received a medical injection, the percentage of last medical injections for which the syringe and needle were taken from a new, unopened package, by background characteristics, Ghana 2014

Note: Medical injections are those given by a doctor, nurse, pharmacist, dentist or other health worker. Figures in parentheses are based on 25-49 unweighted cases.
na = Not applicable

Among both women and men, the proportion who received medical injections in the past 12 months increases with education and wealth.

Table 13.15 further shows that, on average, women received 0.8 medical injections and men received 0.6 medical injections in the preceding 12 months.

Ninety-eight percent of both women and men age 15-49 who received a medical injection in the past 12 months reported that their last injection was given with a syringe and needle taken from a new, unopened package. There are no major variations by background characteristics.

13.14 HIV/AIDS-RELATED KNOWLEDGE AND BEHAVIOUR AMONG YOUNG PEOPLE

This section addresses HIV/AIDS-related knowledge among young Ghanaians age 15-24 and assesses the extent to which young people are engaged in behaviours that may place them at risk of contracting HIV.

Table 13.16 shows the composite indicator, comprehensive knowledge about AIDS, and knowledge of a source of condoms among young people, by background characteristics. The results show that 20 percent of young women and 27 percent of young men have comprehensive knowledge of AIDS.

Among young women age 15-24, this knowledge is highest for those age 20-24 (22 percent), never-married women (22 percent), young women in urban areas (23 percent), and those with a secondary or higher education (32 percent).

Similarly, comprehensive knowledge of AIDS is highest for men age 23-24 (32 percent), never-married young men who have ever had sexual intercourse (30 percent), men in urban areas (32 percent), and men with a secondary or higher education (43 percent).

Condom use is a vital component in the prevention of STIs and HIV transmission, as well as prevention of unintended pregnancies. Young adults are often at a higher risk of contracting STIs because they are more likely to experiment with sex before marriage. Knowledge of a source of condoms helps young people to obtain and use condoms. As shown in Table 13.16, there is a gap in knowledge of a condom source between men and women age 15-24. A higher percentage of young men than young women know at least one condom source (88 percent versus 72 percent). Knowledge of a condom source generally increases with age and is highest among young respondents who are never-married but have ever had sex. For both women and men, knowledge of a condom source is highest among those living in urban areas and those with a secondary or higher education.

Percentage of young women and young men age 15-24 with comprehensive knowledge about AIDS and percentage with knowledge of a source of condoms, by background characteristics, Ghana 2014

[1] Comprehensive knowledge means knowing that consistent use of condoms during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention of the AIDS virus. The components of comprehensive knowledge are presented in Tables 13.2, 13.3.1 and 13.3.2.
[2] For this table, the following responses are not considered a source for condoms: friends, family members, and home.

13.15 AGE AT FIRST SEXUAL INTERCOURSE AMONG YOUNG PEOPLE

In Ghana, HIV transmission occurs primarily through sexual intercourse between an HIV-positive person and an HIV-negative person. Age at first sexual intercourse marks the beginning of the period in which young adults are most likely to be exposed to the risk of contracting HIV. Age at first sex is also an important indicator of exposure to the risk of pregnancy and sexually transmitted infections. Young people who initiate sexual intercourse at an early age are typically at higher risk of becoming pregnant or contracting an STI than those who delay the onset of sexual activity. Consistent condom use can reduce such risks.

Table 13.17 shows the percentage of young women and men who had sexual intercourse before age 15 and before age 18, by background characteristics. More women than men have had sex by age 15 and 18. Eleven percent of young women and 9 percent of young men had their first sexual intercourse before the age of 15, while 47 percent of young women and 32 percent of young men had their first sexual intercourse by age 18.

As expected, the proportion of youth age 15-24 initiating sexual intercourse by age 15 is higher among those who have ever been married than among those who were not yet married at the time of the survey. Rural women age 15-24 are more likely than their urban counterparts to have initiated sex before age 15 (13 percent and 8 percent, respectively). The reverse is seen among young men; 10 percent had sexual intercourse by age 15 in urban areas compared with 7 percent in rural areas. Young people with primary education are most likely to have sexual intercourse by age 15 (21 percent of women and 16 percent of men), and those with a secondary or higher education are least likely to have done so (4 percent of women and 6 percent of men). Similarly, among women and men age 18-24, those with primary level education are substantially more likely to have had sexual intercourse before age 18 than other young respondents (68 percent and 41 percent, respectively).

Table 13.17 Age at first sexual intercourse among young people

na = Not available
[1] For this table, the following responses are not considered a source for condoms: friends, family members and home.

Figure 13.2 shows trends in age at first sexual intercourse among young women and men in the period between 2003 and 2014. Data show that the percentage of young women 15-19 who had sexual intercourse before age 15 has increased from 7 percent in 2003 to 8 percent in 2008 and 12 percent in 2014. For young men, it has increased from 4 percent in 2003 and 2008 to 9 percent in 2014. The percentage of women age 18-19 who have had sexual intercourse by age 18 increased from 52 percent in 2003 to 58 percent in 2014, with a dip in 2008 (50 percent). For men, this percentage has increased steadily from 28 percent in 2003 to 37 percent in 2014.

□ GDHS 2003   ▨ GDHS 2008   ■ GDHS 2014
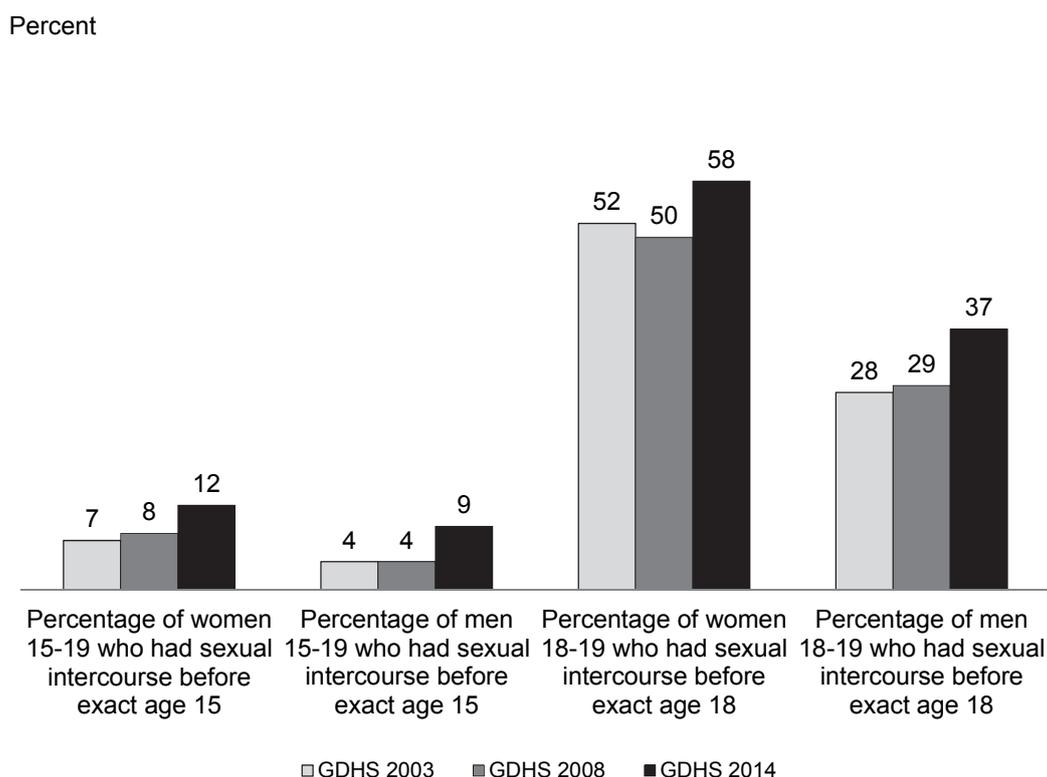

13.16 PREMARITAL SEX

Age group 15-24, which typically spans a period of life including sexual debut and marriage, is a time when premarital sexual intercourse is likely to take place. The length of the interval between sexual initiation and marriage, among other factors, influences the spread of HIV.

Table 13.18 shows the percentage of never-married women and men age 15-24 that have never had sexual intercourse, the percentage who engaged in sexual intercourse in the past 12 months, and, among those who had sexual intercourse within the past 12 months, the percentage that used a condom during their most recent sexual encounter.

Overall, 47 percent of women and 56 percent of men age 15-24 have never had sexual intercourse. Young women and men age 15-17 have a relatively high level of abstinence (74 percent and 84 percent, respectively). Youth who live in urban areas and those with primary education are less likely to have ever had sexual intercourse than youth with other background characteristics.

Table 13.18 shows that, among young women age 15-24, 40 percent had sexual intercourse in the past 12 months. Of those, only 20 percent reported using a condom during their last sexual encounter. Among young men age 15-24, 32 percent had sexual intercourse in the past 12 months. Of those, 41 percent used a condom during their last sexual intercourse. The percentage of youth who had sexual intercourse in the past 12 months increases with age as expected, however there are no marked differences by age in condom use at last sexual intercourse. Condom use increases with level of education.

Table 13.18 Premarital sexual intercourse and condom use during premarital sexual intercourse among youth

Among never-married women and men age 15-24, the percentage who have never had sexual intercourse, the percentage who had sexual intercourse in the past 12 months, and, among those who had premarital sexual intercourse in the past 12 months, the percentage who used a condom at the last sexual intercourse, by background characteristics, Ghana 2014

13.17 MULTIPLE SEXUAL PARTNERS AMONG YOUTH

The most common means of transmission of HIV in Ghana is through unprotected sex with an infected person. To prevent HIV transmission, it is important that young people practice safe sex. Tables 13.19.1 and 13.19.2 present data on the percentage of young people who engaged in sexual intercourse with more than one partner in the 12 months before the survey and the percentage that used a condom during their last sexual encounter.

Young men are more likely than young women to report having multiple sexual partners in the 12 months preceding the survey (8 percent versus 2 percent). In general, as expected, the percentage of young men and young women who reported having sexual intercourse with more than one partner in the past 12 months increases with age. In addition, having multiple sexual partners is more common among never-married young women and ever-married young men, and is higher among women in urban areas and men in rural areas. The percentage of young people with multiple sexual partners is lowest among those who have no education (less than 1 percent for women and 5 percent for men). More than 1 in 10 (11 percent) of young men with a secondary or higher education have multiple sexual partners.

Among young women and men who had multiple partners in the past 12 months, only 15 percent and 34 percent, respectively, reported using a condom during their last sexual intercourse.

Table 13.19.1 Multiple sexual partners in the past 12 months among young people: Women

Among all young women age 15-24, the percentage who had sexual intercourse with more than one sexual partner in the past 12 months, and among those having more than one partner in the past 12 months, the percentage reporting that a condom was used at last intercourse, by background characteristics, Ghana 2014

13.18 AGE MIXING IN SEXUAL RELATIONSHIPS

A substantial proportion of new HIV infections occur among young women age 15-29. In many societies, young women have sexual relationships with men who are considerably older than they are. This practice can contribute to the spread of HIV and other STIs because if a younger, HIV-negative partner has sexual intercourse with an older, HIV-positive partner, this can introduce the virus into a younger, uninfected cohort.

This section examines the prevalence of sexual intercourse between partners with large age differences. Women age 15-19 who had sexual intercourse in the past 12 months were asked the age of all of their partners. In the event they did not know a partner's exact age, they were asked if the partner was older or younger than they were and, if older, whether the partner was 10 or more years older.

Table 13.20 shows that, among women age 15-19 who had sex in the 12 months preceding the survey, 8 percent had sexual intercourse with a man 10 or more years older. A higher percentage of young women in rural areas had sexual intercourse with a man 10 or more years older than themselves. The likelihood of a woman having sexual intercourse with an older man increases with age, and is higher among women who have ever been married. Sexual intercourse between women age 15-19 and men 10 or more years older appears to decrease with increasing education.

There were no reported cases among young men age 15-19 of having a sexual partner during the 12 months preceding the survey who was 10 or more years older than themselves (data not shown).

Table 13.20 Age-mixing in sexual relationships among women age 15-19

13.19 RECENT HIV TEST AMONG THE YOUTH

An individual's decision to know his or her HIV status can provide motivation to practice safer sex, to access care and treatment, and to live an affirmative life. People who learn that they do not have HIV may decide to take precautions in the future to avoid contracting the virus, and those who learn that they are carrying the virus can take actions to seek treatment and avoid transmitting the virus to others.

Table 13.21 presents information on HIV testing among sexually active youth. Among young women and men age 15-24 who have had sexual intercourse in the past 12 months, only 16 percent of women and 3 percent of men were tested for HIV and received their test results in the 12 months preceding the survey. Among young women, recent HIV testing is more common among those who are ever-married. Coverage of HIV testing is higher among women and men who know where to get a condom and those living in urban areas.

Table 13.21 Recent HIV tests among young people

HIV PREVALENCE

14

Key Findings:

- Only 2.0 percent of Ghanaian adults age 15-49 are HIV positive compared with 2.2 percent in the 2003 GDHS. This difference is not statistically significant.
- The HIV prevalence rate is 2.8 percent among women age 15-49 and 1.1 percent among men age 15-49.
- HIV prevalence is higher in urban areas (2.4 percent) than in rural areas (1.7 percent). Prevalence is highest in Eastern region (2.8 percent) and lowest in Northern region (0.3 percent).
- Less than 1 percent of young people age 15-24 are HIV positive, including 1.5 percent of young women and 0.2 percent of young men. Prevalence among young people is highest in Central region.
- Thirty-eight percent of women age 15-49 and 49 percent of men age 15-49 who are living with HIV had never been tested for HIV previously, down from 84 percent of women and 92 percent of men in the 2003 GHDS.
- About 1,700 cohabiting couples were tested for HIV in the 2014 GDHS. In 0.8 percent of couples, both partners were HIV positive. In 2.4 percent of couples, one partner was HIV positive and the other was HIV negative. In 96.7 percent of couples, both partners were HIV negative.

This chapter presents information on coverage of HIV testing, prevalence of HIV, and the factors associated with HIV infection among women and men. The data on HIV prevalence provide important information to plan the national response, to evaluate programme impact, and to measure progress on the Ghana HIV and AIDS National Strategic Plan: 2011-2015. Understanding the factors that influence the prevalence of HIV in the population, along with analysis of the social, biological, and behavioural factors associated with HIV, provide new insights into the HIV epidemic in Ghana that enable more precise targeting of messages and interventions.

In Ghana, as in much of sub-Saharan Africa, national HIV prevalence estimates have been derived primarily from HIV sentinel surveillance (HSS) that focuses on testing pregnant women who attend antenatal clinics. Since 1992, for 12 weeks each year, pregnant women seeking antenatal care (ANC) for the first time and patients newly diagnosed with sexually transmitted infections (STIs) attending STI clinics in the sentinel sites are tested for HIV using an anonymous, unlinked method, and the results are entered into a database, analysed, and reported by the National AIDS/STI Control Programme (GHS 2003). The latest round of sentinel surveillance was conducted between September and December 2014.

While information from the ANC surveillance system has been useful for monitoring trends in HIV levels, the inclusion of HIV testing in the GDHS offers the opportunity to better understand the magnitude and patterns of infection levels in the general reproductive-age population. The GDHS results can also be used to improve the calibration of annual sentinel surveillance data, so that trends in HIV infection can be more accurately measured in the intervals between general population surveys. In addition, the GDHS data have the added advantage of providing behavioural data linked to HIV prevalence, which can be used to guide HIV prevention programmes.

The methodology for HIV testing is described in detail in chapter 1. This chapter addresses the results of the testing and provides information on HIV testing coverage rates among eligible survey respondents. It also compares HIV prevalence estimates from the 2003 GDHS and 2014 GDHS and discusses levels and differentials in HIV prevalence among those tested.

14.1 COVERAGE RATES FOR HIV TESTING

Table 14.1 shows the percent distribution of women and men eligible for HIV testing by testing status, according to urban-rural residence and region. HIV tests were conducted for 95 percent of the 4,927 eligible women and 90 percent of the 4,609 eligible men. For both sexes combined, coverage was 93 percent, with rural residents more likely to be tested than their urban counterparts (95 percent and 91 percent, respectively). There were marked differences in HIV testing coverage by region. Coverage was highest in Northern where 96 percent of women and men were tested, and lowest in Greater Accra, where 87 percent of eligible women and men were tested. Coverage was higher among women than men in every region.

Individuals who were not tested can be categorised into four groups based on the reason for non-response. Four percent of eligible women and men refused testing when asked for informed consent by the health worker (Table 14.1). Two percent were absent for testing and 1 percent were missing test results for some other reason, such as insufficient blood volume, poor specimen quality, lost specimens, non-corresponding bar codes, etc.

Refusal is the most important reason for non-response on the HIV testing component, with men twice as likely to refuse testing as women (6 percent and 3 percent, respectively). Refusal rates are lower in the 2014 GDHS (2 percent of women and 4 percent of men) than in the 2003 GDHS (6 percent of women and 11 percent of men).

[1] Includes all dried blood spot (DBS) samples tested at the lab and for which there is a result, i.e., positive, negative, or indeterminate. Indeterminate means that the sample went through the entire algorithm, but the final result was inconclusive.
[2] Includes: 1) other results of blood collection (e.g., technical problem in the field), 2) lost specimens, 3) non-corresponding bar codes, and 4) other lab results such as blood not tested for technical reason, not enough blood to complete the algorithm, etc.

Coverage is lower in urban areas than in rural areas among both women and men. The urban-rural differential in coverage is most marked for refusal rates, which are 6 percent in urban areas compared with 3 percent in rural areas. Regional variation in coverage rates can also be explained in large part by variation in refusal rates. Refusal rates are highest in Greater Accra among both women (6 percent) and men (13 percent), followed by the Central region (5 percent of women and 9 percent of men), and Ashanti

(4 percent of women and 9 percent of men). For both women and men, absence is relatively high in Upper West, Central and Greater Accra.

Table 14.2 shows coverage of HIV testing by background characteristics. Coverage rates for HIV testing among women were 93 percent or above across all age groups. Among men, coverage rates for HIV testing by age group range from 87 percent to 94 percent.

Table 14.2 Coverage of HIV testing by selected background characteristics

[1] Includes all dried blood spot (DBS) samples tested at the lab and for which there is a result, i.e., positive, negative, or indeterminate. Indeterminate means that the sample went through the entire algorithm, but the final result was inconclusive.
[2] Includes: 1) other results of blood collection (e.g., technical problem in the field), 2) lost specimens, 3) non-corresponding bar codes, and 4) other lab results such as blood not tested for technical reason, not enough blood to complete the algorithm, etc.

By level of education, testing coverage is slightly lower among respondents with secondary school or higher than other respondents, for both women and men. Participation in HIV testing is slightly higher among women and men in households in the lower wealth quintiles than those in households in the upper wealth quintiles.

Additional tables describing the relationship between participation in HIV testing and characteristics related to HIV risk are presented in Appendix A (Tables A.7-A.10). Overall, the results in Tables A.7-A.10 do not show a systematic relationship between participation in testing and variables associated with a higher risk of HIV infection.

14.2 HIV PREVALENCE

14.2.1 HIV Prevalence by Age and Sex

Results from the 2014 GDHS indicate that 2.0 percent of Ghanaian adults are living with HIV (Table 14.3). HIV prevalence in women age 15-49 is 2.8 percent, while for men 15-59 it is 1.1 percent. The HIV gender ratio of three to one (female-to-male) is higher than that found in most population-based studies in Africa. The high female-to-male ratio implies that young women are particularly vulnerable to HIV infection compared with young men. Prevalence is consistently higher among women than among men in all age groups. At the same time, HIV prevalence shows an age pattern among women and men: prevalence generally increases with age, leveling off after age 44. The peak prevalence among women is at age 40-44 (5.4 percent), while prevalence rises gradually with age among men to peak at age 35-39 (2.7 percent).

Table 14.3 HIV prevalence by age

Among de facto women age 15-49 and men age 15-59 who were interviewed and tested, the percentage HIV positive, by age, Ghana 2014

	Women		Men		Total

na = Not applicable

Without treatment, few HIV-positive children survive into their teenage years. As such, youth who are HIV positive may have acquired their infection recently, that is, after becoming sexually active Thus HIV prevalence among youth can serve as an indicator of trends in both prevalence and incidence. Ghana is characterised by the UNAIDS classification scheme as having a low-level generalised HIV epidemic with HIV prevalence that consistently exceeds 1 percent among pregnant women.

A comparison of the 2003 GDHS and 2014 GDHS HIV prevalence estimates indicates that HIV prevalence for all adults age 15-49 remains essentially unchanged—the small decrease from 2.2 percent in 2003 to 2.0 percent in 2014 is not statistically significant. As shown in Figure 14.1, the confidence intervals (CIs) for the 2003 and 2014 HIV prevalence estimates for all adults age 15-49 almost entirely overlap (1.8-2.5 and 1.6-2.4, respectively). Prevalence among women age 15-49 increased from 2.7 to 2.8 percent, and prevalence among men age 15-49 decreased from 1.5 percent to 1.1 percent. However, none of these differences are statistically significant. For women, the confidence interval for the 2014 estimate is 2.2-3.4, compared with 2.2-3.2 reported in 2003. For men, the confidence interval is 0.7-1.6 compared with 1.0-1.9 reported in the 2003 GDHS.

Figure 14.1 HIV prevalence among all adults age 15-49 by sex, Ghana 2003 and 2014
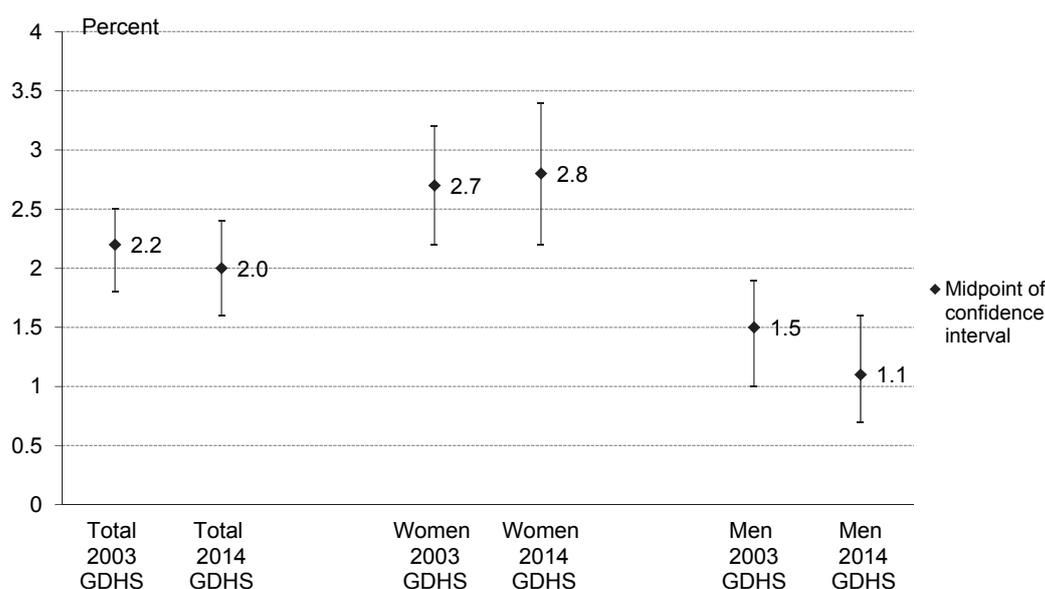

A comparison of HIV prevalence estimates for the 15-19 age group between the 2003 GDHS (0.3 percent) and the 2014 GDHS (0.3 percent) shows that HIV prevalence has remained stable for this age group. This finding is encouraging because of the prospects of achieving Millennium Development Goal (MDG) 6, which calls for halting and beginning to reverse the spread of HIV/AIDS by 2015.

14.2.2 HIV Prevalence by Socio-economic Characteristics

Table 14.4 shows the variation in HIV prevalence among women and men age 15-49 by socio-economic characteristics. Differences by socio-economic characteristics are small. Nevertheless, several observations warrant attention. As Table 14.4 shows, urban residents are only slightly more likely to be HIV positive than rural residents (2.3 percent versus 1.7 percent). Urban women are three times as likely to be HIV positive as urban men, and rural women are two times as likely to be HIV positive as rural men. However, there is no significant difference between the 2014 and 2003 estimates of HIV prevalence among Ghanaian adults in urban areas—2.4 percent in 2014 (1.8-3.0 percent) compared with 2.3 percent in 2003 (1.7-2.0 percent)—or in rural areas—1.7 percent in 2014 (1.2-2.2 percent) compared with 2.0 percent in 2003 (1.6-2.5 percent).

The HIV epidemic shows regional variation. Prevalence is relatively highest in Eastern (2.8 percent), Western (2.7 percent), and Greater Accra (2.5 percent) and lowest in Northern, Upper East and Upper West (less than 1 percent each). Gender differences are apparent in all the regions, with women having consistently higher prevalence than men.

There is no clear correlation between level of education and HIV prevalence. However, respondents with only primary education (2.8 percent) are most likely to have HIV when compared with respondents in the other education categories. Employment status is related to HIV prevalence among both women and men. Women and men who have been employed in the past 12 months are slightly more likely to have HIV than those who have not been employed in the past 12 months, although the difference is small. There is no clear correlation between household wealth status and HIV prevalence, although prevalence is higher among those living in households in the middle three wealth quintiles than among those living in households in the lowest and highest wealth quintiles, for both women and men.

The highest HIV prevalence by religion is in the Pentecostal or Charismatic religion (2.9 percent), followed by Catholic, other Christian faiths, and those with no religion (1.9-2.3 percent). Prevalence

among those in the Anglican, Methodist, Presbyterian group and among those in Islam is 1.1 percent and 1.0 percent, respectively, whilst it is only 0.2 percent among those in the Traditional or Spiritualist group.

The ethnic group with the highest HIV prevalence is Ga or Dangme (4.5 percent), followed by Guan (3.3 percent), and Ewe (2.7 percent). The Mole-Dagbanis have an HIV prevalence of 0.6 percent. HIV prevalence is higher among women than men in most ethnic groups, with the exception of Grusi, Gurma, and Mande, among whom HIV prevalence is higher for men than women.

14.2.3 HIV Prevalence by Other Socio-demographic and Health Characteristics

Marital status is related to HIV prevalence (Table 14.5). Prevalence is substantially higher among widowed women (14.9 percent), followed by divorced or separated women (3.1 percent), and women who are married or living with a man as if married (3.0). Among men, prevalence is highest among divorced or separated men (2.8 percent). Women who report they have had sex but have never been in a union are more likely to have HIV than their male counterparts. HIV infection among women and men who have never been in a union and have never had sex is 0.3 percent.

Table 14.5 HIV prevalence by demographic characteristics

Percentage HIV positive among women and men age 15-49 who were tested, by demographic characteristics, Ghana 2014

An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
na = Not applicable

Prevalence is slightly higher among women in a non-polygynous union (3.3 percent) than among women in a polygynous union (1.3 percent) or not currently in union (2.7 percent). Among men, prevalence is also higher among those in a non-polygynous union (2.6 percent). The differential in HIV prevalence between women and men is greater among those not currently in union than those in union—among women and men not currently in union, women are four times as likely as men to have HIV.

Women who were pregnant at the time of the survey had an HIV prevalence rate comparable to that of women who were not pregnant and women who were unsure of their pregnancy status (2.8 percent each).

The survey results show that men and women who slept away from home 1-2 times in the 12 months preceding the survey have higher HIV prevalence (2.8 percent) than those who have not slept away from home (1.6 percent) or have slept away from home more often (2.1-2.4 percent). Among men, those who slept away from home five or more nights were the most likely to have HIV.

Men and women who stayed away from home less than one month during the past 12 months have a higher HIV prevalence (2.7 percent) than those who had stayed away for more than one month (2.0 percent). Those who did not stay away from home at all were least likely to have HIV (1.6 percent).

Male circumcision has been shown to reduce the risk of HIV acquisition in men. Randomised-control trials in South Africa, Kenya, and Uganda, have documented that the protective effect of male circumcision is significant (Auvert et al. 2005). Table 14.5 presents data on the relationship between HIV prevalence and male circumcision among men age 15-49 who were tested for HIV in the 2014 GDHS and who responded to the question about their circumcision status. Men who were circumcised are six times as likely to be HIV positive as men who were not circumcised (1.2 percent versus 0.2 percent). This is in contrast to the assertion above. Although male circumcision in Ghana is nearly universal (96 percent, see Table 13.13) there are sufficient cases of uncircumcised men to allow a comparison of HIV prevalence by circumcision status at the national level. It should be noted, however, that this finding is only a bivariate association, and the distribution of other risk factors such as place of residence and number of sexual partners, by circumcision status, may also play a role.

14.2.4 HIV Prevalence by Sexual Risk Behaviour

Chapter 13 (Table 13.2) has shown that knowledge and use of HIV prevention methods in the general population is relatively high (70 percent among women and 82 percent among men), yet risky behaviours, such as multiple sexual partners and a lack of consistent use of condoms, are common and therefore remain a major public health concern. Table 14.6 presents HIV prevalence by sexual behaviour characteristics among respondents who have ever had sexual intercourse. In reviewing these results, it is important to remember that responses about sexual risk behaviours may be subject to reporting bias. Also, sexual behaviour in the 12 months preceding the survey may not adequately reflect lifetime sexual risk nor is it possible to know the sequence of events (e.g., whether any reported condom use occurred before or after HIV transmission).

There is no clear relationship between age at sexual debut and HIV prevalence. Overall, HIV prevalence is lowest among men and women who were age 20 or older at the time of their first sexual intercourse. Although the difference in prevalence by age at first sex is small, especially among men, it appears that the relationship between age at first sex and HIV prevalence is different among women and men. Among women, those who initiated sexual activity before the age of 18 are more likely to have HIV than those who had first sex at age 18 or older. Among men, HIV prevalence is slightly higher among those who had first sex at older ages.

The association of HIV prevalence with multiple sexual partners and with partner concurrency was examined in the 2014 GDHS. A respondent was considered to have a concurrent partner if he or she had overlapping sexual partnerships with two or more people during the 12 months before the survey. This includes men with two or more wives.

Among women, HIV prevalence is highest among those who had no sexual partners (4.9 percent) in the 12 months before the survey, followed by women with two or more partners (2.8 percent). Among men, HIV prevalence is highest among those with one sexual partner in the past 12 months (1.7 percent).

Table 14.6 HIV prevalence by sexual behaviour

Note: Total includes 195 cases for whom information on age at first sexual intercourse is missing, 1 case for whom information on multiple sexual partners and partner concurrency in past 12 months is missing, 4 cases for whom information on condom use at last sexual intercourse in past 12 months is missing, and 25 cases from whom information on number of lifetime partners is missing. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
na = Not applicable
[1] A respondent is considered to have had concurrent partners if he or she had overlapping sexual partnerships with two or more people during the 12 months before the survey. (Respondents with concurrent partners include polygynous men who had overlapping sexual partnerships with two or more wives).

Among both women and men, HIV prevalence increases with increasing number of lifetime partners from 0.8 percent among those with 1 partner to 3.4 percent among those with 5-9 partners, and then decreases, unexpectedly, to 1.6 percent among those with 10 or more lifetime partners.

Table 14.6 shows there is no clear relationship between condom use at last sexual intercourse and HIV status among women or men. HIV prevalence among women who used a condom during their most recent sexual intercourse in the 12 months preceding the survey varied little compared with those who did not use a condom during their last sexual intercourse. In contrast, men who used a condom during their most recent sexual intercourse during the same period were slightly less likely to have HIV than men who did not use a condom (0.8 percent and 1.6 percent, respectively).

The HIV prevalence estimate among men who paid for sex during the 12 months preceding the survey is 2.1 percent, compared with 1.4 percent among men who did not pay for sex during this time.

In summary, the results presented in Table 14.6 do not demonstrate a consistent relationship between sexual risk behaviour and HIV prevalence. Additional analysis may be necessary to understand these relationships because they are often confounded by other factors associated with both behavioural measures and HIV prevalence such as age, marital status, and residence. In addition, because HIV prevalence rates are low overall, even when differences in prevalence are linked to behaviour, the ultimate meaning may be difficult to interpret.

14.3 HIV PREVALENCE AMONG YOUNG PEOPLE

Table 14.7 shows that HIV prevalence among those age 15-24 is low (0.8 percent); 1.5 percent of young women and 0.2 percent of young men are HIV positive. Women contract HIV at an earlier age than men. By age 23-24, 4.7 percent of women have HIV compared with only 0.4 percent of their male counterparts.

In contrast to the population age 15-49, among young people age 15-24 those in urban areas have slightly lower HIV prevalence (0.6 percent) than those in rural areas (1.1 percent). This relationship is seen for both women and men.

HIV prevalence among Ghanaian youth is highest in Central region (2.9 percent), followed by youth in Brong Ahafo region (1.1 percent), while all other regions have a prevalence of less than 1 percent. Young women in Central region have the highest HIV prevalence (4.4 percent) while those in Western region and Brong Ahafo region have 1.5 percent each. All regions reported HIV prevalence among young men of less than 0.1 percent, except Central and Brong Ahafo regions (1.2 percent and 0.7 percent, respectively).

Table 14.7 HIV prevalence among young people by background characteristics

Table 14.8 shows HIV prevalence among young people age 15-24 by sexual behaviour. Because of overall low HIV prevalence in this population, the variations shown in Table 14.8 are difficult to interpret. However, it does appear that young people who used a condom at the last sexual intercourse in the 12 months preceding the survey had lower HIV prevalence than those who did not use a condom (0.5 percent versus 1.6 percent).

Table 14.8 HIV prevalence among young people by sexual behaviour

(Respondents with concurrent partners include polygynous men who had overlapping sexual partnerships with two or more wives).

14.4 HIV PREVALENCE BY OTHER CHARACTERISTICS RELATED TO HIV RISK

Table 14.9 shows the differences in HIV prevalence by various characteristics related to HIV risk among men and women who have ever had sex. As expected, women and men with a history of sexually transmitted infection (STI) or STI symptoms have slightly higher HIV rates than those with no history of STIs or STI symptoms (2.9 percent versus 2.2 percent).

Table 14.9 HIV prevalence by other characteristics

Percentage HIV positive among women and men age 15-49 who ever had sex and were tested for HIV, by whether had an STI in the past 12 months and by prior testing for HIV, Ghana 2014

	Women		Men		Total	
Characteristic	Percentage HIV positive	Number	Percentage HIV positive	Number	Percentage HIV positive	Number

Women who have been tested for HIV in the past are more likely to be HIV positive than those who have never been tested. Among women who have ever had sex, HIV prevalence is 4.0 percent among those who have ever been tested for HIV in the past and received the results, compared with 2.5 percent among those who have never been tested. Among men who have ever had sex, HIV prevalence is higher among those who have ever been tested and did not receive their results (4.2 percent), compared with those who have never been tested (0.9 percent).

Table 14.10 provides further information about the relationship between prior HIV testing and the actual HIV status of respondents, according to the results of the 2014 GDHS blood test. The results show that more than half of individuals who are HIV positive (55 percent) have been tested previously and received the results of their last test. This represents a substantial increase from the 2003 GDHS, in which only 12 percent of HIV-positive women and 8 percent of HIV-positive men had been previously tested. However, a little less than half of HIV-positive respondents have either never been tested (41 percent) or have not received the results of their last test (4 percent) and therefore do not know that they should seek out care and treatment or that they can transmit HIV if they have unprotected sex.

Table 14.10 Prior HIV testing according to current HIV status

Percent distribution of women and men age 15-49 by prior HIV testing, according to current HIV status (HIV positive or HIV negative), Ghana 2014

HIV testing prior to the survey	Women		Men		Total	
	HIV positive	HIV negative	HIV positive	HIV negative	HIV positive	HIV negative
Previously tested						
Received result of last test	58.9	42.6	(43.8)	19.3	55.0	31.6
Did not receive result of last test	3.1	6.2	(7.6)	2.2	4.2	4.3
Not previously tested	38.0	51.2	(48.6)	78.5	40.8	64.0
Total	100.0	100.0	100.0	100.0	100.0	100.0
Number	126	4,318	44	3,839	170	8,156

Note: Figures in parentheses are based on 25-49 unweighted cases.

Fifty-nine percent of women who tested positive for HIV in the 2014 GDHS reported that they had been tested before the survey and knew the results of their last test, compared with 43 percent of women who tested negative for HIV. This is a major increase compared with the 2003 GDHS, which reported figures of 12 percent and 7 percent, respectively. Coverage of HIV testing among HIV-positive men also appears to have increased since 2003. It should be noted that testing for HIV depends on a number of factors including access to testing facilities as well as campaigns at the community level to encourage people to learn their HIV status. It is likely that the substantial increase in the number of HIV testing sites since 2003, and nationwide public education on the need to get tested for HIV, account for this observed increase in the proportion of persons who had been tested for HIV and received their test results.

14.5 HIV PREVALENCE AMONG COUPLES

Over 1,700 cohabiting couples were tested for HIV in the 2014 GDHS. Results shown in Table 14.11 indicate that, for the vast majority of cohabiting couples (96.7 percent), both partners are HIV negative; both partners were HIV positive in only 0.8 percent of couples. In an additional 0.8 percent of couples, the woman is HIV negative and the man is HIV positive; conversely, in 1.7 percent of couples, the woman is HIV positive and the man is HIV negative.

The fact that there are more couples that are discordant for HIV than couples that are both HIV positive (2.5 percent and 0.8 percent, respectively) points to an unmet need for HIV prevention because it is likely that the majority of these couples do not mutually know their HIV status. Couple-oriented voluntary counselling and testing (CVCT) services, where partners (including those in polygynous marriages) go together and receive results together should be advocated for at all HIV testing centres in Ghana.

Couples in which the man is age 40 to 49, couples where the woman is older than the man, couples in a non-polygynous union, urban couples, couples living in Western region, couples with primary education, and couples in the second wealth quintile have slightly higher HIV prevalence than other couples.

Table 14.11 HIV prevalence among couples

Percent distribution of couples living in the same household, both of whom were tested for HIV, by HIV status, according to background characteristics, Ghana 2014

Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] A respondent is considered to have had multiple sexual partners in the past 12 months if he or she had sexual intercourse with 2 or more people during this time period. (Respondents with multiple partners include polygynous men who had sexual intercourse with 2 or more wives.)
[2] A respondent is considered to have had concurrent partners if he or she had overlapping sexual partnerships with two or more people during the 12 months before the survey. (Respondents with concurrent partners include polygynous men who had overlapping sexual partnerships with two or more wives).

ADULT HEALTH AND LIFESTYLE

15

> **Key Findings:**
>
> - Among eligible respondents age 15-49, 13 percent of women and men have high blood pressure or are currently taking medicine to lower their blood pressure.
> - Sixty-three percent of women and 86 percent of men are not aware that they have high blood pressure.
> - Only 17 percent of women and 6 percent of men with hypertension are taking medication and have their blood pressure under control.
> - Women and men with a higher-than-normal body mass index (25.0 or higher) are more likely to have high blood pressure.
> - More than 8 in 10 women (83 percent) and about 9 in 10 men age 15-49 (89 percent) have heard of tuberculosis.
> - Seventy-eight percent of women and 81 percent of men age 15-49 correctly know that tuberculosis is spread through the air by coughing.
> - Thirty-three percent of women and 25 percent of men age 15-49 would want to keep a family member's TB status a secret.
> - Less than 1 percent of women age 15-49 and 4 percent of men age 15-49 smoke cigarettes.
> - More than 6 in 10 women and half of men are covered by health insurance. The National/District Health Insurance (N/DHIS) is the most common type of health insurance (62 percent of women and 48 percent of men).
> - Overall, 8 in 10 women and men (79 percent and 82 percent, respectively) who are covered by N/DHIS were satisfied with the services the last time they were treated at a health facility.

Around the world, in developed and developing countries, the rapid increase in noncommunicable diseases (NCDs) is becoming a challenge to achieving global progress in improving population health. Chronic diseases—diabetes, cardiovascular disease, cancer, and chronic respiratory disease—contribute to almost 60 percent of deaths globally, and 80 percent of these deaths occur in developing countries. With each passing day, this death toll will rise unless proper measures are taken. Based on current trends, NCDs will account for 73 percent of deaths and 60 percent of the disease burden in developing countries by 2020 (WHO 2010a). Cardiovascular health can be improved through healthier life choices, such as a healthy diet, regular physical activity, and smoking cessation.

In Ghana, the high prevalence of lifestyle-related diseases and conditions creates a dual burden, given that the country already has a high number of infectious diseases that require significant human and financial resources to control. This creates a need to influence people's knowledge, behaviours, and attitudes to enable them to make healthy lifestyle choices. More effort needs to be aimed at preventing diseases and promoting a healthy lifestyle rather than treating diseases and managing complications. These efforts would greatly benefit from research and reliable data to develop evidence-based policies and programmes for action.

This chapter provides evidence the status of adult health and lifestyle in Ghana. Information includes prevalence, treatment, and awareness of high blood pressure, household use of salt, consumption of fruits and vegetables, tobacco use, as well as knowledge on health issues such as tuberculosis (TB). It also presents information on health insurance coverage and client satisfaction with health care services.

Findings presented in this chapter will inform public health policies targeted at improving adult lifestyles and reducing NCDs in Ghana.

15.1 BLOOD PRESSURE

High blood pressure, or hypertension, is one major risk factor for cardiovascular disease. Health facility-based records indicate that hypertension is the leading cause of disability among adults in Ghana.

The 2014 GDHS is the first national survey in Ghana to include measurements of blood pressure among adults. High blood pressure can lead to fatal complications (Addo et al. 2012). Therefore, in addition to blood pressure measurements, eligible respondents were asked several questions to determine their history of hypertension and treatment.

15.1.1 History and Treatment of High Blood Pressure

As mentioned, survey respondents were asked about their history of hypertension, including whether they had ever been told by a doctor or other health professional that they had high blood pressure and, if so, whether they had been told that on two or more occasions. If they reported being told one or more times that they had high blood pressure, they were asked additional questions about specific actions they were taking to lower their blood pressure.

Table 15.1 shows that, overall, 8 percent of women and 4 percent of men age 15-49 reported being told by a health professional that they have high blood pressure or hypertension. As expected, the percentages increased with age, especially among women. For example, less than 1 percent of women age 15-19 had been told they have high blood pressure, compared with 22 percent of women age 45-49. Obese women and men (BMI greater than 30.0) are more likely than other respondents with a lower BMI to have a history of hypertension. Women and men in urban areas are slightly more likely than those in rural areas to have been told by a health professional that they have high blood pressure. By region, prevalence of high blood pressure is highest among women in Greater Accra (13 percent) and men in Ashanti (7 percent). The percentage told that they have high blood pressure or hypertension increases steadily by education among men (and among women for those with no education, primary education, or middle/JSS/JHS education).

Hypertension is often seen as a disease of the rich. The 2014 GDHS data indeed show that the proportion of respondents who have been told by a health professional that they have hypertension is highest among women and men in the wealthiest households (12 percent and 7 percent, respectively).

Table 15.1 History of hypertension

Percentage of women and men age 15-49 who were ever told by a health professional that they have hypertension or high blood pressure, by background characteristics, Ghana 2014

	Women		Men

[1] Body mass index is expressed as the ratio of weight in kilograms to the square of height in metres (kg/m^2).

Table 15.2 shows that, among respondents ever told that they have high blood pressure, 73 percent of women and 46 percent of men were told on two or more occasions. Looking at specific actions to lower blood pressure among respondents with a history of hypertension, 72 percent of women and 65 percent of men were taking prescribed medication; 51 percent of women and 69 percent of men were controlling or losing weight; 73 percent of women and 75 percent of men were cutting down on salt; 49 percent of women and 75 percent of men were exercising; 21 percent of women and 57 percent of men were cutting down alcohol intake; and 13 percent of women and 43 percent of men had stopped smoking. This information is useful to health programmers when planning health education campaigns and messages targeting hypertension.

Table 15.2 History of hypertension and actions taken to lower blood pressure

Among respondents age 15-49 who had ever been told that they have hypertension or high blood pressure, the percentage who were told on two or more different occasions by a health professional that they have hypertension or high blood pressure and the percentage taking specific actions to lower blood pressure, Ghana 2014

Told on two or more occasions they have hypertension or high blood pressure/actions taken to lower blood pressure	Women	Men
Told on two or more different occasions that they had high blood pressure	72.9	46.2
Actions taken to lower blood pressure		
Taking prescribed medication	71.8	64.6
Controlling or losing weight	51.0	68.5
Cutting down salt in their diet	72.8	74.6
Exercising to control hypertension	49.1	74.5
Cutting down on alcohol intake	21.3	57.3
Stopped smoking	13.3	42.9
Number of respondents who had ever told they have high blood pressure or hypertension by a health professional	703	165

15.1.2 Coverage Rates for Blood Pressure Measurement

The 2014 GDHS is the first national survey in Ghana to measure blood pressure among consenting adults age 15-49. All women and men interviewed were eligible for blood pressure measurement. More than 99 percent of women and men of varied background characteristics consented. Because Table 15.3 presents coverage statistics, the numbers are the unweighted number of women and men who were interviewed and eligible for blood pressure measurement.

Table 15.3 Coverage of blood pressure measurement among women and men

Percentage of women and men age 15-49 eligible for blood pressure measurements, by testing status, according to background characteristics (unweighted), Ghana 2014

Background characteristic	Women		Men	
	Percentage measured for blood pressure	Number of women	Percentage measured for blood pressure	Number of men

15.1.3 Prevalence of High Blood Pressure

To measure blood pressure, the survey interviewers used a fully automatic, digital device with upper-arm pressure inflation and pressure release. Interviewers trained to use the device according to the manufacturer's recommended protocol. Three measurements of systolic and diastolic blood pressure (measured in millimetres of mercury [mmHg]) were taken during the survey interview, with an interval of at least 10 minutes between measurements. The average of the second and third measurements was used to classify individuals with respect to hypertension, following internationally recommended categories (WHO 1999). Individuals were classified as hypertensive if their systolic blood pressure was 140 mmHg or higher or if their diastolic blood pressure was 90 mmHg or higher. Elevated blood pressure was classified as mild, moderate, or severe, according to the cutoff points recommended by the World Health Organization and the National Institutes of Health (WHO 1999; NIH 1997).

Blood pressure status	Systolic (mmHg)		Diastolic (mmHg)
Optimal	<120	and	<80
Normal	120-129	or	80-84
High normal	130-139	or	85-89
Level of hypertension			
Grade 1, mild	140-159	or	90-99
Grade 2, moderate	160-179	or	100-109
Grade 3, severe	180+	or	110+

Following internationally recommended guidelines, individuals were also considered hypertensive if they had a normal average blood pressure reading but were taking antihypertensive medication.

Tables 15.4.1 and 15.4.2 show the prevalence of hypertension among survey respondents age 15-49. Thirteen percent of women and men age 15-49 were classified as hypertensive; that is, they had a systolic blood pressure of at least 140 mmHg or a diastolic blood pressure of at least 90 mmHg at the time of the survey, or they were currently taking antihypertensive medication to control their blood pressure. The term "hypertension" as used in this report is not meant to be a clinical diagnosis of the disease; rather, it is intended to provide an indication of the disease burden in the population at the time of the survey.

As expected, the prevalence of hypertension is positively associated with increasing age; it is lowest among women and men age 15-19 (2 percent and 3 percent, respectively) and highest among women age 45-49 (38 percent) and men age 50-59 (34 percent). Sixteen percent of women and men in urban areas are considered hypertensive, compared with 10 percent of women and 9 percent of men in rural areas. Among women, prevalence of hypertension is highest in Greater Accra (17 percent) and lowest in Upper West (5 percent). Among men, it ranges from 6 percent in the Northern and Upper East regions to 18 percent in the Ashanti region. By education, prevalence of hypertension is highest among women with middle/JSS/JHS education and among men with secondary or higher education (15 percent). The prevalence of hypertension increases with increasing wealth among both women and men.

Although the overall rates of hypertension are relatively low, hypertension is a serious health problem among respondents who are obese (27 percent of women and 51 percent of men). A first step toward bringing hypertension under control is increasing awareness by individuals of their condition and its implications in terms of premature disability and death. Educating the population about the adverse effects of hypertension and promoting blood pressure screening, particularly for older and obese individuals, should be an important focus of health programmes.

Table 15.4.1 Blood pressure status: Women

Among women age 15-49, prevalence of hypertension, percent distribution of blood pressure values, and percentage having normal blood pressure and taking medication, by background characteristics, Ghana 2014

		Classification of blood pressure								
		Normal			Elevated

[1] An individual was classified as having hypertension if he/she had a systolic blood pressure level of 140 mmHg or above or a diastolic blood pressure level of 90 mmHg or above at the time of the survey or was currently taking antihypertensive medication to control his/her blood pressure. The term "hypertension" as used in this table is not meant to be a clinical diagnosis of the disease; rather, it provides an indication of the disease burden in the population at the time of the survey.
[2] Body mass index is expressed as the ratio of weight in kilograms to the square of height in metres (kg/m[2]).

Figure 15.1 shows the level of awareness and treatment status of women and men classified as hypertensive based on the survey measurements. More than 6 in 10 women (63 percent) and 8 in 10 men (86 percent) who had high blood pressure based on survey measurements reported that they were unaware of their condition. Only 17 percent of hypertensive women and 6 percent of hypertensive men were being treated and had brought their blood pressure under control, and 16 percent of women and 5 percent of men were being treated but still had elevated blood pressure. Four percent of hypertensive women and 3 percent of hypertensive men were aware that they had elevated blood pressure but were not being treated for it.

Figure 15.1 Awareness of high blood pressure and treatment status among women and men age 15-49 with high blood pressure
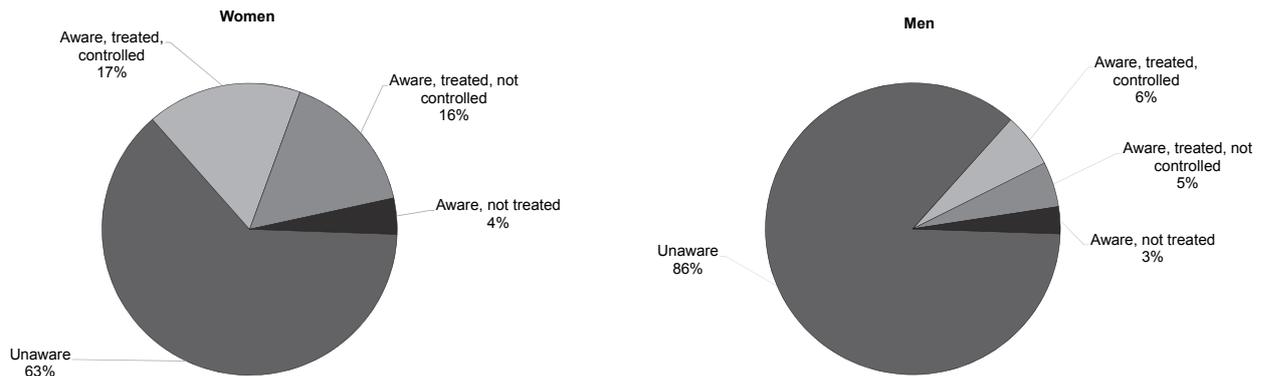

15.2 CONSUMPTION OF FRUITS AND VEGETABLES

Over the last decade, regenerative health has established a firmer foothold in the field of public health in Ghana. This has become possible mainly due to the introduction of the Regenerative Health and Nutrition (RHN) health risk-reduction programme initiated by the Ghanaian Ministry of Health (RHNP 2006).

Adequate nutrition, especially sufficient intake of fruits and vegetables, is essential for good health and general wellbeing. The 2014 GDHS respondents were asked a number of questions on the consumption of fruits and vegetables over the last seven days. Table 15.5 shows the mean number of days during the past week that women and men age 15-49 consumed fruits and vegetables, by background characteristics. On average, women and men consumed fruit on three of the previous seven days and vegetables on four of the previous seven days.

Differences by background characteristics in the mean number of days that respondents consumed fruit and vegetables in the past week are minimal.

Table 15.5 Consumption of fruit and vegetables

Mean number of days during the week preceding the survey that women and men 15-49 consumed fruits and vegetables, by background characteristics, Ghana 2014

Background characteristic	Women			Men		
	Mean number of days in the past week respondent consumed fruit	Mean number of days in the past week respondent consumed vegetables	Number of women	Mean number of days in the past week respondent consumed fruit	Mean number of days in the past week respondent consumed vegetables	Number of men

15.3 HOUSEHOLD USE OF SALTY FOODS

Salt intake is an important factor in controlling high blood pressure, cardiovascular disease, and stroke. The 2014 GDHS collected information from eligible women age 15-49 on household consumption of salty foods in the last 24 hours.

Table 15.6 shows that a high proportion of women (84 percent) reported that someone in their household consumed processed foods with salt in the last 24 hours; 7 in 10 (70 percent) reported that a household member used bouillon cubes; more than one-third (36 percent) reported use of salted, dried fish; about one in five (21 percent) reported use of processed or canned meat, fish, or legumes; and about one in four (24 percent) reported use of other processed foods with salt.

Use of salty foods is high in both urban and rural areas. There are regional variations in household use. For example, 92 percent of women in Northern region reported use of bouillon cubes, as compared with 62 percent of women in Greater Accra. On the other hand, use of processed or canned meat, fish, or legumes is lowest in the Northern region (7 percent) and highest in the Volta region (39 percent). Use of bouillon cubes decreases with wealth, while use of processed or canned meat, fish, or legumes increases

with wealth. Variations in the use of other salty components by wealth do not follow a particular pattern. There is a slight decline in use of foods processed with salt as wealth increases.

Table 15.6 Household use of salty foods

Percentage of women age 15-49 who reported that a household member cooked food using salty ingredients in the 24 hours preceding the survey, by ingredient, according to selected background characteristics, Ghana 2014

Background characteristic	Percentage of women who reported that a household member cooked food using salty ingredients in the 24 hours preceding the survey by ingredient:					Number of women
	Bouillon cubes	Processed or canned meat, fish, or legumes	Salted, dried fish	Other processed foods with salt	Any processed foods with salt

15.4 KNOWLEDGE OF IODISED SALT AND ITS PERCEIVED BENEFITS

It is essential that the population is well informed about the benefits and sources of iodised salt. Table 15.7 shows the percentage of women age 15-49 who have ever heard of iodised salt, and among women who have heard of it, the percentage who know of specific benefits of using iodised salt and the percentage who know how to recognise iodised salt.

More than 8 in 10 women age 15-49 have heard of iodised salt. This proportion is lowest among women age 15-19 (80 percent), those living in rural areas (81 percent), and women in Brong Ahafo (70 percent). Knowledge of iodised salt increases substantially with education and wealth.

Among women who have heard of iodised salt, 49 percent believe that use of iodised salt provides energy, 34 percent believe that it prevents goiter, and 21 percent believe that it improves intelligence. Some variations in perceived benefits of iodised salt use are observed by background characteristics. The percentage of women who perceive that iodised salt use improves intelligence and prevents goiter is higher in urban than in rural areas and increases markedly by education and wealth. Regional variations also exist. For example, the proportion of women who believe that use of iodised salt provides energy ranges from 14 percent in Upper West to 58 percent in Brong Ahafo.

When asked if they can distinguish iodised from non-iodised salt, about half of women said they can recognise it as a fine powdered salt (52 percent) or by looking at the iodised salt logo (48 percent). Only 7 percent of women reported that iodised salt could be distinguished from non-iodised salt through salt testing. There are variations by background characteristics. The proportion of women who can identify iodised salt as a fine powdered salt is higher in rural than in urban areas. This percentage is highest among women in Upper West region (85 percent). The proportion of women who can identify iodised salt as a fine powdered salt decreases with women's increasing education and wealth. By contrast, the percentage of women who can recognise iodised salt by looking at the iodised salt logo is higher in urban areas and increases with increasing education and wealth.

Table 15.7 Knowledge of iodised salt and perceived benefits of using iodised salt

Percentage of women 15-49 who have ever heard of iodised salt, and among women who ever heard of iodised salt, percentage who know of specific benefits of using iodised salt and percentage who know how to recognise iodised salt by specific ways, according to background characteristics, Ghana 2014

Background characteristic	Percentage of women who have ever heard of iodised salt	Number of women	Percentage of women who know of specific benefits:								Percentage of women who can recognise iodised salt by specific ways:				Number of women who heard of iodised salt
			Improves intelligence	Provides energy	Prevents still birth	Prevents mental retardation	Prevents miscarriages	Prevents goiter	Other benefits	Don't know	By testing salt	By looking at iodised salt logo	Fine powdered salt	Don't know

15.5   KNOWLEDGE AND ATTITUDES ON TUBERCULOSIS

Tuberculosis (TB) is a communicable disease caused by *Mycobacterium tuberculosis*. Transmission is mainly airborne through droplets coughed or sneezed out by infected persons. The infection is primarily concentrated in the lungs, but in some cases can be transmitted to other areas of the body. Mortality among TB-infected individuals is high, as the disease leads to poor lung function, acid-base imbalance, and death.

Tuberculosis is, however, curable. The cure rates in persons infected have been directly proportional to knowledge of the disease, as well as the ability of persons to seek early treatment. The Ghana Society for the Prevention of Tuberculosis was established in 1954 to support efforts by the Ghanaian government to control TB. Control of tuberculosis has remained a priority for the country. The current strategies of the National Tuberculosis Control Programme include TB-related health education, regular supply of medications, TB surveillance, training of health personnel on TB treatment and control, and directly observed supervision of treatment or DOTS.

The 2014 GDHS collected information from women age 15-49 and men age 15-59 on knowledge of and attitudes toward TB. Specifically, respondents were asked whether they had ever heard of the illness, how it spreads from one person to another, whether it can be cured, and whether they would want to keep the information secret if a member of their family contracted TB. This information is useful in policy formulation and implementation of programmes designed to combat and limit the spread of TB, and in addressing issues of discrimination.

Table 15.8 shows that knowledge of tuberculosis is high in Ghana. More than 8 in 10 women (83 percent) and about 9 in 10 men age 15-49 (89 percent) have heard of TB. Seventy-eight percent of women and 81 percent of men age 15-49 correctly responded that TB is spread through the air by coughing. A lower proportion of respondents age 15-19 (70 percent of women and 72 percent of men) responded that TB is spread through the air by coughing, compared with older respondents. Knowledge is higher among urban than among rural respondents. Regional variations exist. For instance, knowledge among women that TB is spread through the air by coughing ranges from 59 percent in Upper West to 84 percent in Central and Volta. Knowledge increases with education and wealth among both women and men. For instance, 68 percent of women and 64 percent of men with no education report that TB is spread through the air by coughing, compared with 90 percent and 91 percent, respectively, of women and men with a secondary or higher education.

More than 8 in 10 women and men age 15-49 (85 and 89 percent, respectively) believe that TB can be cured. Differences across subgroups are similar to those observed for the other TB knowledge components.

When asked whether they would want to keep a family member's TB status a secret, 33 percent of women and 25 percent of men age 15-49 responded that they would. Among both women and women, the proportion who reported that they would want to keep a family member's TB status a secret is highest in the youngest age group 15-19 (42 percent and 33 percent, respectively). This percentage is highest among women in Upper East and men in Ashanti (51 percent each). For women, fear of stigma regarding TB generally decreases with education and wealth, while the opposite is true for men, as fear of stigma noticeably increases with increasing education and wealth.

Table 15.8 Knowledge and attitude concerning tuberculosis

Percentage of women and men age 15-49 who have heard of tuberculosis (TB), and among those who have heard of TB, the percentages who know that TB is spread through the air by coughing, the percentage who believe that TB can be cured, and the percentage who would want to keep secret that a family member has TB, by background characteristics, Ghana 2014

Background characteristic	Among all respondents:		Among respondents who heard of tuberculosis, percentage who:			
	Heard of TB	Number of respondents	Know that tuberculosis is spread through air by coughing	Believe tuberculosis can be cured	Would want a family member's tuberculosis kept secret	Number of respondents

15.6 TOBACCO USE

Smoking has a powerful, negative impact on population health. Smoking is a known risk factor for cardiovascular disease, it causes lung cancer and other forms of cancer, and it contributes to the severity of pneumonia, emphysema, and chronic bronchitis. It may also have an impact on individuals who are exposed to secondhand smoke. For example, inhaling secondhand smoke may adversely affect children's growth and cause childhood illnesses, especially respiratory diseases. Because smoking is an acquired behaviour, all morbidity and mortality caused by smoking is preventable.

With the release of its new policy recommendations in 2007, WHO signalled the urgent need for countries to make all indoor public places and workplaces 100 percent smoke-free to reduce population exposure to secondhand tobacco smoke.[1] In Ghana, tobacco regulations are itemised in Articles 61 to 68 of the Public Health Act of 2012 (Act 851). The Act, in Article 64, clearly prohibits the sale of tobacco without adequate labelling of its health hazards. Further legal provision for incorporating tobacco education on the hazards of smoking into school health programmes is given in Article 66 (4) of Act 851. The Act affirms Ghana's commitment to the WHO Framework Convention on tobacco control (WHO 2003).

Women and men interviewed in the 2014 GDHS were asked about their smoking habits. Tables 15.9.1 and 15.9.2 show the percentage of women and men who smoke cigarettes or use tobacco, according to background characteristics. Due to the small numbers of female and male smokers (5 and 253, respectively), a breakdown of the number of cigarettes smoked in the last 24 hours by background characteristics is not shown. Less than 1 percent of women age 15-49 smoke cigarettes, and less than 1 percent use other tobacco. Differences by background characteristics are minimal, although 3 percent of women in Northern use tobacco.

Table 15.9.1 Use of tobacco: Women

Percentage of women age 15-49 who smoke cigarettes or a pipe or use other tobacco products, according to background characteristics and maternity status, Ghana 2014

Table 15.9.2 shows that smoking is somewhat more common among men than women; 4 percent of men smoke cigarettes or a pipe, and 2 percent use other tobacco. Table 15.9.2 shows that smoking is more common among men than women; 4 percent of men age 15-49 smoke cigarettes or a pipe, and 2 percent use other tobacco. The likelihood of a man using tobacco increases with age and decreases with increasing education and wealth. As is true of women, men in Northern are the most likely of all the regions to use tobacco (11 percent).

Among men who smoke cigarettes, 27 percent smoked 1-2 cigarettes, 37 percent smoked 3-5 cigarettes, 16 percent smoked 6-9 cigarettes, and 14 percent smoked 10 or more cigarettes within the past 24 hours (data not shown).

15.7 HEALTH INSURANCE

15.7.1 Health Insurance Coverage

The National/District Health Insurance Scheme (N/DHIS) is a national health care financing policy introduced to promote universal access to health care in Ghana. In 2003, the scheme was passed into law by Act 650. The Ghana National Health Insurance Authority was established to license, monitor, and regulate the operation of health insurance schemes in the country. In 2012, Act 650 was repealed and replaced with Act 852, which presently governs health insurance practices in Ghana.

Tables 15.10.1 and 15.10.2 show the percentage of women and men age 15-49, respectively, by type of health insurance coverage, according to background characteristics. More than 6 in 10 women (62 percent) and about half of men age 15-49 (48 percent) reported that they are covered by the National/District Health Insurance Scheme. One percent or less of women and men are covered by other types of insurance.

Thirty-eight percent of women and 51 percent of men report that they are not covered by any type of the health insurance scheme, a sharp decrease from 60 percent of women and 70 percent of men age 15-49 as reported in the 2008 GDHS.

There are no major variations in N/DHIS coverage by age or residence for women. Among men, those age 25-29 are the least likely to be covered by this type of insurance (39 percent), and urban men are somewhat more likely than those living in rural areas to do so (50 percent versus 46 percent). N/DHIS coverage levels range from 48 percent of women in Central and 37 percent of men in Western to 85 percent and 74 percent, respectively, of respondents in Upper West. Women and men who have a secondary or higher education and those in the wealthiest households are the most likely to be covered by the National/District Health Insurance Scheme when compared with other subgroups.

In the 2014 GDHS, respondents who answered that they were *not covered* by any health insurance scheme were further probed to find out if they were *registered* with the National/District Health Insurance Scheme[1]. The purpose of this question is to gather information on individuals who, even though they reported they were not covered by any health insurance, may have been registered with N/DHIS but did not hold valid N/DHIS cards. This could be due to various reasons, such as: they were registered but had not fully paid for the membership; they had not yet received the membership card; or they were in the waiting period.

Table 15.11 shows the percentage of women and men age 15-49 who reported they were registered with N/DHIS (even though they reported they were not covered by any health insurance), by background characteristics. Overall, 18 percent of women and 13 percent of men reported they were registered with N/DHIS. There are no major variations by background characteristics, except for place of residence for men and region for both women and men. Rural men are more likely than those living in urban areas to be registered with N/DHIS (16 percent versus 11 percent). For women, N/DHIS registration level ranges from 3 percent in Upper West to 33 percent in Ashanti, and, for men, it ranges from 4 percent in Upper East to 20 percent, each, in Brong Ahafo and Western.

---

[1] This question was not asked in the 2008 Ghana DHS survey.

15.7.2 Health Insurance Payment

Respondents who reported that they were covered by N/DHIS were further asked who paid for their N/DHIS membership. Tables 15.12.1 and 15.12.2 show the percentage of women and men, respectively, who were covered by N/DHIS by the person who paid their membership, according to background characteristics.

Overall, 94 percent of women and 99 percent of men covered by N/DHIS paid for their membership, 6 percent of women and 1 percent of men were exempt and did not have to pay. Slightly less than 4 in 10 women and 6 in 10 men age 15-49 (37 and 60 percent, respectively) paid for the N/DHIS membership themselves. Older respondents, those employed for cash, women who are formerly married, and men who are currently or formerly married are most likely to have paid for N/DHIS membership themselves or to have had their membership paid for by a relative, friend, or employer. Variations by other background characteristics are not pronounced.

It is notable that relatives paid for N/DHIS membership for more than half of women (54 percent) and for one-third of men (33 percent).

Only 3 percent of women and 7 percent of men age 15-49 said that their insurance was paid for by their employer. There are minimal differences by background characteristics among women; however, some variations exist among men. The percentage of men whose N/DHIS membership was paid for by

their employer is highest among those age 35-39 (12 percent), those employed for cash (9 percent), those who are formally married (12 percent), those in urban areas (9 percent), those in Greater Accra (15 percent), and men in the wealthiest households (15 percent).

<u>Table 15.12.1 Payment for N/DHIS coverage: Women</u>

15.7.3 Possession of a Valid N/DHIS Card

Respondents who reported that they were covered by N/DHIS were also asked if they held a valid membership card, and if so, if they could show it to the interviewer. Possession of a valid N/DHIS card enables the insured client to access health care services.

Table 15.13 shows the possession of a valid N/DHIS card and whether or not the card was seen by the interviewer. Overall, more than 8 in 10 respondents (88 percent of women and 83 percent of men) who were covered by N/DHIS had a valid card (seen or unseen by the interviewer). One-third of women (33 percent) and about one in five men (19 percent) were not able to show the N/DHIS card at the time of the interview.

Twelve percent of women and 17 percent of men who are covered by N/DHIS did not have a valid membership card. The proportion who did not have a card is especially high among women in Northern, Greater Accra, and Upper West (33 percent, 26 percent, and 25 percent, respectively) and among men in Greater Accra, Eastern, and Upper West (37 percent, 33 percent, and 29 percent, respectively).

The median duration of waiting time to receive N/DHIS membership card is 11 weeks for both women and men. The waiting time is shorter for women in their late 20s (about 8 weeks), for women and men in urban areas (8 weeks and 9 weeks, respectively), respondents in Greater Accra (about 2 weeks each), and those in the wealthiest households (4 weeks for women and 7 weeks for men).

Table 15.13 Possession of a valid N/DHIS card

Percent distribution of women and men age 15-49 covered by the National/District Health Insurance Scheme (N/DHIS) by possession of a valid N/DHIS card and whether or not card was seen by interviewer, and among respondents with a valid N/DHIS card, median number of weeks respondent waited to receive card, according to background characteristics,, Ghana 2014

15.7.4 Out-of-Pocket Payments

Women and men covered by N/DHIS were asked whether they made out-of-pocket payments for medicines and services. Table 15.14 shows that more than one-third of respondents (37 percent of women and 35 percent of men) who were covered by N/DHIS paid out of pocket for medicines and services at some time before the survey. More than 6 in 10 respondents (61 percent of women and 63 percent of men) did not make any out-of-pocket payments for medicines and services.

Differences across subgroups by background characteristics are small. Young respondents age 15-19 are the least likely to pay out of pocket for medicines or services (27 percent of women and 19 percent of men). Respondents who are employed for cash (41 percent of women and 38 percent of men), those who are currently or formerly married (38-44 percent of women and 40-41 percent of men), women in urban areas (43 percent), women living in Eastern (61 percent), and men living in Upper East (49 percent) were the most likely to pay out of pocket for medicines or services. The out-of-pocket payments among women who are covered by N/DHIS increases with wealth. Among men, there are no definite patterns in the relationship between out-of-pocket payments and wealth.

Percent distribution of women and men age 15-49 covered by the National/District Health Insurance Scheme (N/DHIS) by whether they made out-of-pocket payments for medicines and services, according to background characteristics, Ghana 2014

na = Not applicable

Women and men who reported they were registered with N/DHIS were also asked whether they made out-of-pocket payments for medicines and services prior to the survey. More than half of women (55 percent) and 6 in 10 men (60 percent) who are registered with N/DHIS reported that they paid out of pocket for medicines and services at some time before the survey (data not shown).

15.7.5 Need for Services Not Covered Under N/DHIS

Women and men covered by N/DHIS were also asked whether there were any services they needed from a health provider that were not covered by N/DHIS. Table 15.15 shows that about one-third of women and men (33 percent and 32 percent, respectively) reported that they needed additional services that were not covered by N/DHIS.

Women and men in their teenage years (15-19) are the least likely to have a need for services not covered by N/DHIS. Data further shows that women and men who are employed for cash (39 percent

each), those who are formerly married (45 percent and 42 percent, respectively), women in Volta (51 percent), and men in Western (55 percent) are the most likely to have a need for services not covered by N/DHIS. Need for health services not covered by N/DHIS tends to increase with wealth for both women and men.

Table 15.15 Need for health services not covered by N/DHIS

Percent distribution of women and men age 15-49 registered/covered by the National/District Health Insurance Scheme (N/DHIS) by reported need for health services that are not covered by N/DHIS, according to background characteristics, Ghana 2014

na = Not applicable

Among respondents who reported they are registered with N/DHIS, 24 percent of women and 27 percent of men reported that that they needed additional services that were not covered by N/DHIS (data not shown).

15.8 PERCEIVED QUALITY OF SERVICES AND CLIENT SATISFACTION

Respondents who were covered by N/DHIS were asked about their perceptions of the quality of services received by N/DHIS card holders when compared with other clients. Table 15.16 presents data on client satisfaction among respondents who were covered by N/DHIS.

More than one-third of women and men age 15-49 (36 and 34 percent, respectively) who were covered by N/DHIS thought that N/DHIS insured individuals get better service when compared with other clients, and about 3 in 10 women (29 percent) and one-third of men (34 percent) thought that N/DHIS card holders get worse service than other clients. Client dissatisfaction generally increases with increasing household wealth, supporting the notion that residents in the wealthiest households might have higher expectations for quality of services. For example, 20 percent of women and 25 percent of men in the lowest wealth quintile think that N/DHIS card holders get worse service than other clients, compared with 39 percent of women and 40 percent of men in the highest wealth quintile.

Table 15.16 N/DHIS card holders' perceived quality of services received

Respondents registered with N/DHIS were also asked about their perceived quality for services received by N/DHIS card holders when compared with other clients. Twenty-two percent of women and 31 percent of men think that N/DHIS insured individuals get better service when compared with other clients and 43 percent of women and 37 percent of men think that N/DHIS card holders get worse service than other clients (data not shown).

Table 15.17 presents opinions of respondents covered by N/DHIS on the quality of services received the last time they were treated at a health facility. Overall, 8 in 10 women and men (79 percent and 82 percent, respectively) who are covered by N/DHIS said that they were satisfied with the services the last time they were treated at a health facility. While satisfaction in most of the regions is on par with the national levels, only 69 percent of women in the Northern region and 62 percent of men in the Brong Ahafo region reported that the services received the last time they were treated at a clinic or hospital were satisfactory, far below the national average. Nationally, only 12 percent of women and men said that the waiting period was too long, and an even a smaller proportion (6 percent of women and 3 percent of men) said that they did not receive enough information about their illness and treatment from the health provider. Only 2 percent of respondents reported that health staff was not polite during their visit to the health facility. Women in Volta and Northern regions (29 percent and 26 percent, respectively) and men in Brong Ahafo (29 percent) were substantially more likely than other subgroups to say that the waiting period was too long.

Among respondents who said they were not covered by any health insurance but reported they were registered with N/DHIS, 8 in 10 women and men (82 percent and 78 percent, respectively) said that they were satisfied with the services the last time they were treated at a health facility. Nine percent of women and 16 percent of men said that the waiting period was too long, 7 percent of women and 3 percent of men said that they did not receive enough information about their illness and treatment from the health provider, and 2 percent of women and 1 percent of men reported that health staff was not polite during their visit to the health facility (data not shown).

Table 15.17 Client satisfaction among respondents covered by N/DHIS

Percent distribution of women and men age 15-49 covered by the National/District Health Insurance Scheme (N/DHIS) by client satisfaction with most recent visit to a clinic or hospital for treatment, and problem (if any) that occurred during the visit, according to background characteristics, Ghana 2014

15.9 TREATMENT SEEKING AND PERCEIVED QUALITY OF CARE

GDHS respondents were asked if they visited a health facility in the last six months and, if so, what type of facility they visited. Data in Table 15.18 show that 37 percent of women and 15 percent of men age 15-49 visited a health facility in the preceding six months. The percentage who had visited a health facility in the last six months by region is highest among women in Upper West (49 percent) and men in Western (20 percent), and, by education, it is highest among those with a secondary or higher education (42 percent and 21 percent, respectively). While the percentage of women and men who visited a health facility in the six months preceding the survey tends to increase with increasing education and wealth quintile among both women and men, the percentage of men who visited a facility is far lower than among women across all background characteristics.

Among women and men age 15-49 who visited a health facility in the last six months, 78 percent and 65 percent, respectively, visited a public health facility, and 22 percent and 36 percent, respectively, visited a private facility.

Table 15.18 Treatment seeking behaviour among all respondents

Percentage of women and men age 15-49 who visited a health facility in the 6 months preceding the survey, and among women and men who visited a health facility in the 6 months before the survey, percent distribution by type of facility, according to background characteristics, Ghana 2014

The 2014 GDHS also asked respondents who had visited a health facility in the past six months about the types of services they received and methods of payment for their last visit. Table 15.19 shows that, as expected, the highest proportion of women received services for antenatal, delivery, and postnatal care (29 percent), followed by malaria (16 percent). Among men, the highest proportion received services for malaria (33 percent), followed by other outpatient care (16 percent). Only 6 percent of women received family planning services at their most recent visit to a health facility.

Among respondents who visited a health facility in the last six months, 61 percent of women and 50 percent of men paid through the National/District Health Insurance Scheme, and 29 percent and 42 percent, respectively, paid cash for the services they received.

Table 15.19 Type of health services received among all respondents

Percent distribution of women and men age 15-49 by type of service received at most recent visit to a health facility in the 6 months before the survey and percent distribution of women and men age 15-49 by method of payment for services received during most recent visit in the 6 months before the survey, Ghana 2014

As part of the efforts aimed at achieving Millennium Development Goals 4 and 5 (reducing child mortality and improving maternal health), a number of health care interventions are provided for free under N/DHIS for pregnant women and children under age 18. These services include free antenatal and maternity services, emergency obstetric and neonatal care, home visits by community health nurses, immunisation of children under 5, and adolescent health care, including counselling. The 2014 GDHS respondents were asked if they were aware of any programmes that help pregnant women and children under age 18 to access health services for free.

Table 15.20 shows that 66 percent of women and 59 percent of men are aware of services for pregnant women. More than 4 in 10 women (44 percent) and men (47 percent) are aware of services for children under age 18.

Awareness about programmes that help pregnant women and children under 18 to access health services is lowest among respondents age 15-19, among the less educated, and among the poorest respondents. Women in Upper East (39 percent) and men in Upper West (42 percent) have the lowest level of awareness of programmes that help pregnant women access health services. Women in Northern (16 percent) and Eastern (21 percent) are especially unlikely to be aware of programmes that provide help for accessing health services for children under 18.

Table 15.20 Awareness of health services for children and pregnant women

Percentage of women and men age 15-49 who are aware of programmes that help pregnant women and children under age 18 to access health services, by background characteristics, Ghana 2014

In order to assess client satisfaction with different aspects of health care services, all 2014 GDHS respondents who visited a health facility in the preceding six months were asked questions on their level of satisfaction for the services they received during their most recent visit.

Data in Table 15.21 show that a high proportion of clients are either very satisfied or satisfied with various aspects of health care services. Among women, the proportion very satisfied or satisfied ranges from 56 percent for the time they waited for test results to 92 percent, each, for the cleanliness of the facility and for the ease of finding where to go. Among men, the proportion very satisfied or satisfied

ranges from 58 percent for the time they waited for test results, to 90 percent who reported being very satisfied or satisfied with the provider listening to them.

Overall, 12 percent or less of respondents reported not being satisfied with any particular aspect of provision of services, and only 6 percent or less reported being very dissatisfied with the different aspects health services.

Table 15.21 Satisfaction with health services among all respondents

Percent distribution of women and men age 15-49 by satisfaction with various aspects of health services for the most recent visit to a health facility in the 6 months before the survey, Ghana 2014

Aspects of health service provision	Women						Men					
	Very satisfied	Satisfied	Fairly satisfied	Not satisfied	Very dissatisfied	Number of women who visited a health facility in the past 6 months	Very satisfied	Satisfied	Fairly satisfied	Not satisfied	Very dissatisfied	Number of men who visited a health facility in the past 6 months

When asked specifically whether the health provider spent enough time with the respondents and if the provider was friendly during the most recent visit in the past six months, more than 9 in 10 women (93 percent and 95 percent, respectively) and men (92 percent and 95 percent, respectively) responded positively. More than 8 in 10 women and men (88 percent and 82 percent, respectively) answered positively when asked if the provider had sought their consent before providing treatment (data not shown).

WOMEN'S EMPOWERMENT AND DEMOGRAPHIC AND HEALTH OUTCOMES

16

> **Key Findings:**
>
> - The percentage of currently married employed women who earn cash and make independent decisions about how to spend their earnings increased to 63 percent in 2014 from 58 percent in in 2008.
> - Seventy-seven percent of women participate in making decisions regarding their own health care.
> - The percentage of women who agree that a husband is justified in beating his wife for at least one specified reason has dropped— from 37 percent in 2008 to 28 percent in 2014.
> - Contraceptive use increases with women's empowerment.
> - Unmet need for family planning decreases with improvements in women's empowerment.
> - Access to antenatal care, delivery assistance from a skilled provider, and postnatal care within the first two days of delivery go up as women's empowerment increases.
> - Infant, child, and under-5 mortality rates decline with improvements in women's empowerment.
> - Only 7 percent of employed women had maternity leave with pay.
> - Seventy percent of currently married women in Ghana live in marriages where a price was negotiated and paid for the bride.

The 1994 International Conference on Population and Development declared that "advancing gender equality and equity and the empowerment of women and the elimination of all kinds of violence against women, and ensuring women's ability to control their own fertility are cornerstones of population and development-related programs" (United Nations 1994). Women's empowerment has been defined to encompass women having a sense of self-worth, access to opportunities and resources, choices and the ability to exercise them, control over their own lives, and influence over the direction of social change (United Nations Population Information Network 1995).

Ghana is a signatory to almost all the international conventions on human rights, women's rights, and children's rights, as well as to agreements on international goals regarding education, health, and poverty eradication. As a signatory to the Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), adopted in 1979 by the United Nations General Assembly, the government of Ghana promised nodiscrimination, gender equity, and social justice as mandated by the 1992 Constitution of Ghana. The 2003 national plan of action, approved by the government of Ghana for the effective implementation of CEDAW and other documents related to human rights, guarantees all rights per the CEDAW covenants. There is also a plan of action in place to implement all 12 of the Beijing Platform of Action commitments. These commitments include addressing poverty among women, increasing access to education and health resources, and establishing support for programmes to bring women to decision-making levels in all political, constitutional, and administrative units. Currently, Ghana ranks 13 in the world (out of 187 countries) on the Gender Inequality Index.[1]

Data from the 2014 GDHS discussed in earlier chapters show that women in Ghana are predominantly engaged in agriculture. Few have skilled manual jobs, and they are much less likely than men to be engaged in the professional, technical, and managerial fields (see Table 3.6.1). Further, women

---

[1] http://hdr.undp.org/en/countries/profiles/GHA

lag behind men in educational attainment, literacy, and exposure to mass media, all of which are critical contributors to women's empowerment and exert considerable influence on both the development of their personality and on strengthening women's positions in the household and in society in general.

This chapter presents additional data on the status of women in Ghana, including information on gender differences in employment, access to and control over cash earnings, asset ownership, participation in household decision-making, the relative earnings of husbands and wives, and entitlement to maternity leave. The chapter also explores how demographic and health indicators vary by women's empowerment, as measured by the number of decisions in which the woman participates and her ability to negotiate safer sexual relations with her husband. The ranking of women on these indices has been found to be associated with demographic and health outcomes, including contraceptive use, ideal family size, unmet need for family planning, access to reproductive health care and child survival. It also highlights issues of maternity protection and bride wealth negotiations and payments for married women and men in Ghana.

16.1 EMPLOYMENT AND FORM OF EARNINGS

Employment, particularly employment for cash, and control over how earnings are used are important indicators of empowerment for women and men. Table 16.1 shows the percentage of currently married women and men age 15-49 who were employed at any time in the 12 months before the survey and the percent distribution of employed women and men by the type of earnings they received (cash only, cash and in-kind, or in-kind only), if any.

The table shows that 87 percent of currently married women and almost all currently married men (99 percent) age 15-49 were employed in the 12 months preceding the survey. Women age 15-24 are less likely than older women age 25-49 to be employed, while there is no such variation by age among currently married men. The proportion of currently married women who are employed has declined over the past six years (from 91 percent in 2008 to 87 percent in 2014); by contrast, employment among currently married men has seen no change (99 percent in both 2008 and 2014). Employed men and women differ in the type of earnings they receive for their work.

Table 16.1 Employment and cash earnings of currently married women and men

Percentage of currently married women and men age 15-49 who were employed at any time in the past 12 months and the percent distribution of currently married women and men employed in the past 12 months by type of earnings, according to age, Ghana 2014

| Age | Among currently married respondents: | | Percent distribution of currently married respondents employed in the past 12 months, by type of earnings | | | | | |

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

Ninety-three percent of men receive cash only, cash and in-kind, and in-kind only payment compared with 86 percent of women. Fourteen percent of women are not paid for their work at all, compared with 7 percent of men. Thus, not only are currently married women much less likely than currently married men to be employed, they are also much less likely to be paid for the work they perform. Women are more than four times as likely as men (4 and 1 percent, respectively) to be paid in-kind only.

16.2   WOMEN'S CONTROL OVER THEIR OWN EARNINGS AND RELATIVE MAGNITUDE OF WOMEN'S AND THEIR HUSBANDS' EARNINGS

Control over cash earnings is another dimension of empowerment. Currently married women who earn cash for their work were asked who the main decisionmaker is regarding the use of their earnings. They were also asked about the relative magnitude of their earnings compared with their husband's earnings. This information provides insight into women's empowerment within the family and the extent of their control over resources. It is expected that women who are employed and who receive cash earnings are more likely to have control over household resources.

Table 16.2.1 shows the percent distribution of currently married women who received cash earnings in the past 12 months, according to the person who controls their earnings and their perception of the magnitude of their earnings relative to those of their husbands. Sixty-three percent of currently married women who earn cash mainly decide themselves on how their cash earnings are used, one-third make the decision jointly with their husbands, and only 5 percent have the decision made mainly by their husbands. The proportion of currently married women who earn cash for their work and who decide mainly by themselves on the use of their cash earnings has increased from 58 percent in 2008 to 63 percent in 2014, whereas the proportion of women who jointly decide with their husbands on the use of their own earnings has decreased from 36 percent to 32 percent. Overall, the proportion of women who participate alone or jointly with their husbands in decisions about the use of their earnings has increased slightly, from 93 percent in 2008 to 95 percent in 2014.

Table 16.2.1 further shows that decision-making by women alone about the use of women's earnings does not vary much with age. Women with one to four children are more likely than others to decide how to use their cash earnings (65 percent versus 59 to 60 percent). Women's participation in the use of their own earnings varies by urban-rural residence, with urban women slightly more likely to be involved in decision-making. Women with no education and women in the lowest wealth quintile are most likely to decide on how their earnings are used.

There is substantial regional variation in who makes decisions on how women's earnings are used. The proportion of employed women who mainly decide on the use of their earnings is highest in the Northern region (92 percent) and lowest in the Western region (45 percent). Joint decision-making on the use of women's earnings is most common in the Western region (51 percent).

Table 16.2.1 also shows women's perception of their cash earnings relative to their husbands' earnings. Among currently married women who earn cash, 77 percent earn less than their husband, 10 percent earn more, and 8 percent earn about the same. Thus, almost one in five women who have cash earnings in Ghana are likely to earn about the same as or more than their husband.

The proportion of currently married women who are employed, receive only cash, and earn about the same as or more than their husband generally increases with age. However, the proportions vary by number of living children, women's education, and household wealth. Women in the Eastern and Central regions are more likely than women in other regions to earn the same as or more than their husband.

Table 16.2.1 Control over women's cash earnings and relative magnitude of women's cash earnings

Percent distribution of currently married women age 15-49 who received cash earnings for employment in the 12 months preceding the survey by person who decides how wife's cash earnings are used and by whether she earned more or less than her husband, according to background characteristics, Ghana 2014

Background characteristic	Person who decides how the wife's cash earnings are used:					Wife's cash earnings compared with husband's cash earnings:						Number of women

16.3 CONTROL OVER HUSBANDS' EARNINGS

Currently married men age 15-49 who receive cash earnings were asked who—the men themselves, their wife, the husband and wife jointly, or someone else—decides how their own cash earnings are used. In addition, currently married women were asked who decides how their husbands' cash earnings are used. Table 16.2.2 shows that 52 percent of currently married men age 15-49 who receive cash earnings mainly make decisions on how their earnings will be used, while 44 percent decide jointly with their wives. Only 4 percent of men say that decisions on how their earnings are used are made mainly by their wives.

The proportion of currently married men who say that they make decisions about the use of their earnings jointly with their wives is highest among men age 40-44 (49 percent). The proportion of men making decisions alone about the use of their income is higher in urban than in rural areas (54 percent and 49 percent, respectively). However, differentials by education are minimal, as all the categories record proportions hovering around 50 percent, with the exception of men with primary education. The proportion

of men who jointly make decisions about the use of their earnings with their wives is highest among men in the lowest wealth quintile (54 percent).

The main decisionmaker regarding the use of men's own earnings varies greatly by region. Decision-making by the man alone is highest in the Volta (68 percent) and lowest in Upper East and Western regions (31 percent each). Decision-making about men's earnings mainly by the wife is most common in the Western region (19 percent).

Table 16.2.2 also shows women's responses on who makes decisions about their husbands' earnings. Only currently married women whose husbands received cash earnings are included. Fifty-five percent of currently married women whose husbands receive cash earnings say that their husbands alone decide about the use of husbands' cash earnings, 37 percent say that they decide jointly with their husband, and 8 percent say that they decide by themselves.

A comparison between women's responses about the main decision maker regarding the use of their husbands' earnings and men's responses about the use of their own earnings shows similarities and differences. Men are more likely than women to report that they jointly make the decision with their spouse (44 percent and 37 percent, respectively), but women are twice as likely as men to say that the wife is the main decision maker (8 percent and 4 percent, respectively). Further, women are more likely than men to report that the husband is the main decision maker regarding the use of his earnings (55 percent versus 52 percent).

The pattern of variation by background characteristics in women's responses about decisions on the use of their husbands' earnings is similar to that of men's responses. A higher proportion of men age 40-44 report that they make joint decision with their wives (49 percent) while, for women, it is those age 35-39 (41 percent). Among men and women, the proportion in rural areas who report that they make joint decisions (47 percent and 39 percent, respectively) in relation to the use of the husbands' earnings is higher than men and women in urban areas (42 percent and 35 percent, respectively).

Table 16.2.2 Control over men's cash earnings

Percent distributions of currently married men age 15-49 who receive cash earnings and of currently married women age 15-49 whose husbands receive cash earnings, by person who decides how husband's cash earnings are used, according to background characteristics, Ghana 2014

The level of women's earnings relative to their husbands' earnings is expected to be associated with women's control over their own and their husbands' earnings. To examine this association, Table 16.3 shows the percent distribution of currently married women with cash earnings by the person who has the main say in the use of their earnings and the distribution of currently married women by the person who has the main say in the use of their husbands' earnings, according to women's perception of the size of their own earnings relative to their husbands' earnings.

The table shows that women's participation in the decision on the use of their own and their husbands' earnings varies by their relative earnings. However, the variation is not necessarily as expected. The most consistent finding is that women who earn about the same as their husbands are more likely to jointly decide about the use of both their own earnings (60 percent) and their husbands' earnings (63 percent). Women who earn more than their husbands are more likely than other women to be the main decisionmaker about the use of their husbands' earnings (12 percent), but women who earn more and

women who earn less than their husbands are about equally likely to be the main decisionmakers about the use of their own earnings (63 percent versus 65 percent, respectively).

Table 16.3 Women's control over their own earnings and over those of their husbands

Percent distribution of currently married women age 15-49 with cash earnings in the last 12 months by person who decides how the wife's cash earnings are used and percent distribution of currently married women age 15-49 whose husbands have cash earnings by person who decides how the husband's cash earnings are used, according to the relation between wife's and husband's cash earnings, Ghana 2014

16.4 WOMEN'S AND MEN'S OWNERSHIP OF SELECTED ASSETS

Ownership of assets, particularly high-value assets, has many beneficial effects for households, including protection against financial ruin. Women's individual ownership of assets enables their economic empowerment and provides protection in the case of marital dissolution or abandonment. The 2014 GDHS collected information on women's and men's ownership (alone, jointly, and alone and jointly) of two high-value assets: namely, land and a house.

Table 16.4.1 shows that 81 percent of women age 15-49 do not own a house and 78 percent do not own any land. Four percent of women own a house alone, and 8 percent own land alone. Notably, women who own either of these assets appear to own them mostly jointly, as opposed to alone or alone and with someone else. Women's ownership of a house increases with age but decreases with education. Rural women are more likely to own a house and land than those from the urban areas. More women in the Central region own a house (11 percent) and land (16 percent) by themselves than women from the other regions.

na = Not applicable

Table 16.4.2 shows that 78 percent of men age 15-49 percent do not own a house and 67 percent do not own land. Seventeen percent of men age 15-49 own a house alone, and 25 percent own land alone, compared with 4 percent and 8 percent of women, respectively. Ownership of land and a house among men increases with age. Men's ownership of a house declines sharply with education, from 51 percent among men with no education to 14 percent among men with a secondary or higher education. Ownership of land is highest among men with no education (55 percent). Unexpectedly, ownership of a house declines with wealth, and ownership of land varies minimally and inconsistently with wealth. Men in the Upper West region are more likely than men in other regions to own a house (59 percent). Land ownership among men is highest in the Northern region (49 percent).

Women's disadvantage relative to men in land ownership is evident in every demographic and socioeconomic category, and women's disadvantage in home ownership is also evident, especially among those with no education. A higher proportion of men own a house or land alone or jointly, compared with their female counterparts. The proportions of older women and older men owning these high-value assets alone are vastly different. For example, only 15 percent of women age 45-49 own a house alone, and 21 percent own land alone, compared with 40 percent and 54 percent, respectively, of men age 45-49.

Table 16.4.2 Ownership of assets: Men

16.5 WOMEN'S PARTICIPATION IN DECISION-MAKING

The ability of women to make decisions that affect their personal circumstances is an essential element of their empowerment and serves as an important contributor to their overall development. To assess currently married women's decision-making autonomy, the 2014 GDHS collected information on their participation in three types of decisions: their own health care, making major household purchases, and visits to family or relatives. To provide an understanding of gender differences in household decision-making, currently married men were asked the same questions about their participation in decisions about their own health care and major household purchases. Table 16.5 shows the percent distribution of currently married women and men, according to the person in the household who usually makes decisions concerning these matters. Women are considered to participate in decision-making if they make decisions alone or jointly with their husbands.

Table 16.5 shows that 77 percent of women participate in making decisions about their own health care, but only 27 percent decide solely about their own health care. By contrast, the vast majority of men (92 percent) are involved in decisions about their own health care. Only 23 percent of women and 11 percent of men report that they make their own decisions about major household purchases. Slightly over one-quarter of women decide themselves on visits to their family or relatives.

Table 16.5 Participation in decision making

Percent distribution of currently married women and currently married men age 15-49 by person who usually makes decisions about various issues, Ghana 2014

Decision	Mainly wife	Wife and husband jointly	Mainly husband	Someone else	Total	Number of women
		WOMEN				
Own health care	27.4	49.5	22.5	0.5	100.0	5,321
Major household purchases	22.8	51.1	25.3	0.8	100.0	5,321
Visits to her family or relatives	26.4	60.3	12.7	0.5	100.0	5,321
		MEN				
Own health care	7.6	42.8	49.4	0.1	100.0	1,846
Major household purchases	10.5	50.5	38.9	0.1	100.0	1,846

Table 16.6.1 shows how currently married women's participation (alone or jointly) in decision-making varies by background characteristics. The table presents the results for the three specific types of decisions asked about: the woman's own health care, making major household purchases, and visits to her family or relatives. In addition, the table includes two summary indicators: the proportion of women involved in making all three decisions and the proportion not involved in making any of the three decisions.

Table 16.6.1 Women's participation in decision-making by background characteristics

Percentage of currently married women age 15-49 who usually make specific decisions either by themselves or jointly with their husband, by background characteristics, Ghana 2014

Background characteristic	Specific decisions			All three decisions	None of the three decisions	Number of women
	Woman's own health care	Making major household purchases	Visits to her family or relatives

Total	76.9	73.9	86.7	61.6	6.7	5,321

Note: Total includes 1 woman for whom information on employment in the last 12 months is missing.

Table 16.6.1 shows that 62 percent of women report taking part in all three decisions, and less than 1 in 10 (7 percent) report not participating in any of the three decisions. Seventy-four percent of women report taking part in specific decision making on major household purchases, while 87 percent participate in decisions on visits to their parents or relatives. The highest proportion of women who report participation in all three decisions (69 percent) is in the age group 35-39. More women who are in the middle wealth quintile take part in all three decisions (68 percent) than women in the other wealth quintiles. Participation in all three decisions varies minimally and inconsistently with education. Women in rural areas are more likely to participate in all three decisions than women in urban areas (63 percent and 60 percent, respectively). Women's participation in all three decisions ranges from a low of 49 percent in the Upper West region to a high of 84 percent in the Upper East region.

Women may have a say in some and not all other decisions. To assess a woman's overall decision-making autonomy, the decisions in which she participates (i.e., she alone has the final say or does so jointly with her husband) are added together. The total number of decisions in which a woman participates is one simple measure of her empowerment. Figure 16.1 gives the percentage of currently married women, according to the number of decisions in which they participate either alone or jointly with their husband. Only 7 percent of currently married women do not participate in any of the three types of decisions, 11 percent have a say in at least one decision, 21 percent participate in at least two decisions, and 62 percent participate in all three decisions.

Figure 16.1 **Number of decisions in which currently married women participate**

GDHS 2014

Table 16.6.2 presents data on currently married men's participation (alone or jointly) in two types of decisions—their own health care and making major household purchases—by background characteristics. The table shows that 92 percent of men age 15-49 participate in decisions about their own health care, and 89 percent participate in decisions about major household purchases. Overall, 87 percent of currently married men participate in both of these decisions and only 7 percent do not participate in either. The proportion of currently married men participating in both decisions varies slightly with age but tends to decline with education. More men in the second wealth quintile take part in both decisions (94 percent) than men in the other wealth quintiles. Men's participation in both decisions is higher in rural than urban areas (90 percent and 85 percent, respectively). At the regional level, participation in both decisions ranges from 99 percent in the Northern region to 73 percent in the Ashanti region.

Table 16.6.2 Men's participation in decision making by background characteristics

Percentage of currently married men age 15-49 who usually make specific decisions either alone or jointly with their wife, by background characteristics, Ghana 2014

16.6 ATTITUDES TOWARDS WIFE BEATING

The critical problems that women face are many and diverse. One of these problems, and among the most serious, is the issue of violence against women. To assess women's and men's attitudes towards wife beating, respondents were asked whether a husband is justified in hitting or beating his wife in each of the following five situations: if she burns the food, if she argues with him, if she goes out without telling him, if she neglects the children, and if she refuses to have sexual intercourse with him.

Table 16.7.1 shows the percentage of women age 15-49 who agree that a husband is justified in hitting or beating his wife for specific reasons, according to background characteristics. More than one in four women (28 percent) agree that a husband is justified in beating his wife for at least one specified reason. Seven percent of women agree that a husband is justified in hitting or beating his wife if she burns the food, 16 percent if she argues with him, 17 percent if she goes out without telling him, 21 percent if she neglects the children, and 12 percent if she refuses to have sexual intercourse with him. Women's attitudes

towards wife beating have improved since 2008; the proportion of women who agreed that wife beating is justified for at least one of the specified reasons has decreased from 37 percent in 2008 to 28 percent in 2014.

Table 16.7.1 Attitude towards wife beating: Women

Percentage of all women age 15-49 who agree that a husband is justified in hitting or beating his wife for specific reasons, by background characteristics, Ghana 2014

| Background characteristic | Husband is justified in hitting or beating his wife if she: | | | | | Percentage who agree with at least one specified reason | Number of women |

Highest	2.2	4.7	5.6	8.4	3.3	12.3	2,194
Total	7.4	15.6	16.5	20.9	12.2	28.3	9,396

Note: Total includes 1 woman for whom information on employment in the last 12 months is missing.

Women who are employed but do not receive cash, women with more than five children, women who are married or living together, rural women, and women in the Northern region are more likely than their counterparts to agree that wife beating is justified for at least one specified reason. The proportion of women who agree that wife beating is justified for at least one specified reason decreases with increasing education and wealth.

Table 16.7.2 shows the percentage of men age 15-49 who agree that a husband is justified in hitting or beating his wife for each of the specified reasons, according to background characteristics. Thirteen percent of men agree that a man is justified in beating his wife for at least one specified reason. Three percent agree that he is justified in hitting or beating his wife if she burns the food, 6 percent if she

argues with him, 7 percent if she goes out without telling him, 8 percent if she neglects the children, and 5 percent if she refuses to have sexual intercourse with him. Similar to the results reported for women, there has been a marked decrease in the percentage of men who agree that wife beating is justified for at least one specified reason, from 22 percent in 2008 to 13 percent in 2014.

Men age 15-19 who are employed but not for cash, have no living children, have never been married, live in rural areas, and in Upper West region are more likely to agree that wife beating is justified for at least one specified reason than their counterparts. Similar to women, the proportion of men who agree that wife beating is justified for at least one specified reason decreases with increasing education and wealth.

Table 16.7.2 Attitude towards wife beating: Men

Percentage of all men age 15-49 who agree that a husband is justified in hitting or beating his wife for specific reasons, by background characteristics, Ghana 2014

Background characteristic	Husband is justified in hitting or beating his wife if she:					Percentage who agree with at least one specified reason	Number of men

16.7 WOMEN'S EMPOWERMENT INDICATORS

Women's empowerment has important implications for demographic and health outcomes, including women's use of family planning and maternal health care services. Two summary indices of women's empowerment were used to assess the relationship of selected demographic and health outcomes with women's empowerment. The first index is the number of decisions that currently married women participate in alone or jointly. This index, which ranges from 0 (participates in none of the three decisions asked about) to 3 (participates in all three decisions), provides insight into women's control over their daily lives. The second indicator, which ranges in value from 0 to 5, is the total number of reasons for which the respondent feels that a husband is justified in beating his wife. A lower score on this indicator is interpreted as reflecting a greater sense of entitlement and self-esteem and a higher status of women. Table 16.8 shows how these two indicators relate to each other.

Table 16.8 examines the relationship between the two empowerment indices among currently married women age 15-49. In general, the expectation is that women who participate in making household decisions are also likely to have gender-equalisation beliefs. Empowerment is strongest for those women who participate in all decisions and agree that wife beating is not justified for any reason. As expected, the percentage of women who disagree with all the reasons justifying wife beating increases with the number of decisions in which the woman participates. Also, as expected, the percentage of women participating in all household decisions declines directly with the number of reasons the woman believes justify wife beating.

Table 16.8 Indicators of women's empowerment

Percentage of currently married women age 15-49 who participate in all decision making and the percentage who disagree with all of the reasons justifying wife beating, by value on each of the indicators of women's empowerment, Ghana 2014

Empowerment indicator	Percentage who participate in all decision making	Percentage who disagree with all the reasons justifying wife beating	Number of women
Number of decisions in which women participate[1]			
0	na	64.1	355
1-2	na	64.3	1,689
3	na	74.1	3,278
Number of reasons for which wife-beating is justified[2]			
0	64.9	na	3,742
1-2	58.2	na	767
3-4	54.1	na	547
5	40.5	na	265

na = Not applicable
[1] See Table 16.6.1 for the list of decisions.
[2] See Table 16.7.1 for the list of reasons.

16.8 CURRENT USE OF CONTRACEPTION BY WOMEN'S STATUS

A currently married woman's ability to have only the number of children she wants, as well as her use and choice of contraceptive methods, will be affected by her control over her own life, including her sexual relationship with her husband. A woman who is unable to control other aspects of her life may be less able to make decisions regarding her fertility. She may also feel the need to choose contraceptive methods that are less obvious or do not need the approval or knowledge of her husband. Table 16.9 shows the relationship of each of the empowerment indices with current use of contraceptive methods for currently married women.

As expected, contraceptive use is positively associated with both indices of women's empowerment. Use of any contraceptive method and any modern method is higher among women who

participate in one or more decisions and increases with the number of positive attitudes towards safer sexual relations. For example, the percentage of women using any method increases from 20 percent among those who do not participate in any decisions to 29 percent among women who participate in all three decisions. The association between the decision-making index and use of specific family planning methods is most evident for any modern method: the percentage of women using any modern method rises from 18 percent among women who do not participate in any of the household decisions to 24 percent among women participating in all three decisions.

Similarly, contraceptive use is negatively related to the number of reasons for which wife beating is justified. Table 16.9 shows that the percentage using any method decreases from 28 percent of women who did not agree that any of the reasons justified wife-beating to 22 percent among women who agreed that wife beating is justified for any of the five reasons. The proportion using any modern method tends to decrease with the number of reasons for which wife beating is accepted. Conversely, the percentage of women not currently using any method is highest among those women who justified all five reasons for wife-beating (79 percent), compared with those women who do not believe wife-beating is ever justified (72 percent).

Table 16.9 Current use of contraception by women's empowerment

Percent distribution of currently married women age 15-49 by current contraceptive method, according to selected indicators of women's status, Ghana 2014

16.9 IDEAL FAMILY SIZE AND UNMET NEED BY WOMEN'S STATUS

The question about ideal family size required a woman to perform the difficult task of considering the number of children she would choose to have in her whole life regardless of the number (if any) that she had already borne. As a woman becomes more empowered, she is more likely to have a say in the number (ideal family size) and spacing of children she desires. She has more control over her ability to access and use contraceptives to space and limit her family size. Women who have a desire to limit their births but who are not using family planning are defined as having an unmet need for family planning. Table 16.10 shows how currently married women's ideal family size and their unmet need for family planning vary by the two indices of women's empowerment. Women who want to delay their next birth for two or more years (space their next birth) or do not want to have any more births (limit their births), but who are not using family planning, are considered to have an unmet need for family planning.

Table 16.10 shows that more empowered women have a somewhat smaller ideal family size than those who are least empowered. For example, the mean ideal family size among women who agree that wife-beating is justified for all five reasons is 5.6, compared with 4.1 among women who do not agree that wife-beating is justified for any of the reasons.

Unmet need varies inconsistently with the two empowerment indicators. Looking at the relationship between unmet need and women's empowerment indicators, the findings show that unmet need is highest among women who participate in 1-2 of the household decisions (32 percent) and among women who think that wife beating is justified for 3-4 of the reasons (32 percent).

Table 16.10 Ideal number of children and unmet need for family planning by women's empowerment

Mean ideal number of children for women 15-49 and the percentage of currently married women age 15-49 with an unmet need for family planning, by indicators of women's empowerment, Ghana 2014

[3] Restricted to currently married women. See Table 16.6.1 for the list of decisions.
[4] See Table 16.7.1 for the list of reasons.

16.10 REPRODUCTIVE HEALTH CARE AND WOMEN'S EMPOWERMENT

Table 16.11 shows use of antenatal, delivery, and postnatal care services by women's scores on the two empowerment indices. It is expected that empowered women will be more likely to seek health care services that better meet their reproductive health goals, including safe motherhood.

The results in Table 16.11 show that women's empowerment, as expected, is positively associated with women's access to and use of reproductive health services. Women who agree with none of the reasons justifying wife beating are the most likely to have received antenatal care from a skilled provider (98 percent), delivery assistance from a skilled provider (81 percent), and postnatal care soon after delivery (84 percent), compared with women who think that wife beating is justified for all five reasons (92 percent, 47 percent, and 54 percent, respectively).

Table 16.11 Reproductive health care by women's empowerment

Percentage of women age 15-49 with a live birth in the five years preceding the survey who received antenatal care, delivery assistance and postnatal care from health personnel for the most recent birth, by indicators of women's empowerment, Ghana 2014

[1] Skilled provider includes doctor, nurse/midwife, and community health officer/nurse.
[2] Includes women who received a postnatal checkup from a doctor, nurse/midwife, community health officer/nurse, or traditional birth attendant (TBA) in the first two days after the birth. Includes women who gave birth in a health facility and those who did not give birth in a health facility.
[3] Restricted to currently married women. See Table 16.6.1 for the list of decisions.
[4] See Table 16.7.1 for the list of reasons.

16.11 INFANT AND CHILD MORTALITY AND WOMEN'S EMPOWERMENT

The care that children, particularly young children, receive is a result of their household circumstances. In most cases, a child's mother is the person most likely to notice problems with a child's health because of her role as the primary caregiver, and she is therefore likely to be in the best position to make health care choices. Also, a mother's health care before, during, and after pregnancy directly and indirectly influences her child's health, particularly in the early stages of life. There is a positive relationship between higher levels of women's empowerment and better health and chances of survival for children. The ability of women to access information, make decisions, and act effectively in their own interests or in the interests of those who depend on them is essential to their empowerment. In fact, maternal empowerment fits into Mosley and Chen's framework on child survival as an individual-level variable that affects child survival through proximate determinants (Mosley and Chen 1984).

Table 16.12 shows that infant and under-5 mortality rates decline as women's empowerment index scores increase. For example, in the case of women who participate in no decisions, infant mortality is 52 deaths per 1,000 live births and under-5 mortality is 83 deaths per 1,000 live births. This compares unfavourably with 50 deaths and 69 deaths per 1,000 live births, respectively, for women who participate in all three decisions. The relationship between scores for reasons for the justification of wife beating and childhood mortality is not clear. However, among women who justified wife-beating for all five reasons, they are more likely to have a high infant and under-5 mortality rate (54 deaths and 88 deaths per 1,000 live births, respectively), compared with children of women who believe that wife-beating is never justified (49 deaths and 67 deaths per 1,000 live births, respectively).

16.12 ENTITLEMENT TO AND USE OF MATERNITY LEAVE

Maternity protection for working women is essential to their health and well-being and to that of their children. It is crucial to ensure women's access to decent work, as well as to gender equality, as it enables them to combine their reproductive and productive functions and to prevent unequal treatment in employment due to women's reproductive function. To ensure that women are protected during their reproductive period, the 2003 Ghana Labour Act 651 states that employed women are entitled to a period of 12 weeks of maternity leave on production of a medical certificate issued by a health professional showing the expected date of her delivery (in addition to any period of annual leave she is entitled to otherwise). Employed women who are on maternity leave are entitled to be paid fully and receive all the other benefits that they are otherwise entitled to.

Table 16.13 shows the percent distribution of women age 15-49 who were employed at any time in the past 12 months preceding the survey by reported entitlement to maternity leave. Seventy-eight percent of the employed women were not entitled to maternity leave. Only 9 percent of employed women were entitled to maternity leave with pay, while 12 percent could only take maternity leave without pay. Employed women in urban areas are more likely to receive maternity leave with pay (13 percent) than those in rural areas (5 percent). At the regional level, women who are entitled to paid maternity leave range from 16 percent in Greater Accra to as low as 3 percent in the Northern region. Employed women with secondary and higher education and those in the highest wealth quintile are much more likely to enjoy maternity leave with pay than those in the other categories.

Table 16.13 Entitlement to maternity leave

Percent distribution of women age 15-49 who were employed at any time in the 12 months preceding the survey by reported entitlement to maternity leave, according to background characteristics, Ghana, 2014

Table 16.14 shows the percent distribution of women 15-49 with a live birth in the past five years and working at the time of their last birth, percent distribution of women who took maternity leave, and percent distribution of women who took paid maternity leave. Overall, 63 percent of women were working around the time of their last birth. Eighty-one percent of the women working did not take leave, 12 percent took leave without pay, and only 7 percent took paid maternity leave. Women employed by a nonfamily member, earning cash only, and living in urban areas and in Greater Accra are more likely to enjoy maternity leave with pay than those in the other categories. Women with a secondary or higher education are much more likely to go on maternity leave with pay (40 percent) than those with no education or only primary education (1 percent). Similarly, the proportion of women going on maternity leave with pay around the time of their last birth increases with increasing wealth.

Table 16.14 Maternity leave

16.13 LENGTH OF MATERNITY LEAVE

Table 16.15 shows, among women taking paid or unpaid maternity leave, the median number of weeks that women did not work prior to their last birth and the median number of weeks that they did not work following their last birth, according to background and employment characteristics.

Generally, the median number of weeks that women did not work before their last birth is 2 weeks, and the median number of weeks that they did not work after giving birth is 16 weeks. Women who are self-employed stop work for a longer duration before giving birth (4 weeks) and resume work later (17 weeks) than women who are employed by family members and nonfamily members. There are variations in the median number of weeks of stopping work before last birth in relation to women who earn cash only

and those who earn cash and in-kind. Women who earn only cash stop work for a shorter duration before birth than women who earn cash and in-kind (median of 2 weeks versus 4 weeks). However, the median number of weeks that women stop working following birth is similar for both women who earn only cash and those who earn cash and in-kind.

The median number of weeks that women stopped work before and after birth is higher for women age 20-24, compared with women in other age groups. Women in urban areas are more likely to stop work longer after birth (16 weeks) than those in rural areas (12 weeks). At the regional level, Volta region has the highest median number of weeks that women stopped work before birth (4 weeks). On the other hand, the highest median number of weeks that women did not work following their last birth is in Brong Ahafo region (17 weeks). Women in the poorest and wealthiest households have the shortest median number of weeks that they stopped work before and after birth, compared with women in the other wealth quintiles.

Table 16.15 Median number of weeks women do not work before and after birth

Among women taking paid or unpaid maternity leave, median number of weeks that women did not work prior to their last birth and median number of weeks that women did not work following their last birth, according to background and employment characteristics, Ghana 2014

16.14 BRIDEWEALTH NEGOTIATION

One of the characteristics of Ghanaian marriages is the payment of bridewealth. It is an amount of money, property, or wealth paid by the groom or his family to the parents of the bride upon marriage of their daughter to the groom. It signifies the consent of family members to the marriage and also serves as a sign or a token of support for the marriage. The acceptance of the bridewealth by the bride's family represents each family's approval of the other, and it formalises the marriage. Bridewealth symbolises a bond between the bride's and the groom's families.

Table 16.17 presents information on bridewealth among currently married women and men age 15-49. Seventy percent of currently married women in Ghana live in marriages where their bridewealth was negotiated and paid in full, 10 percent had a bridewealth negotiated and partially paid, 2 percent had their bridewealth negotiated but did not pay at all, and 18 percent of the women's bridewealth was not negotiated. Currently married women in rural areas, in the Northern region, those with no education, and women in the lowest wealth quintile are more likely to live in a marriage where their bridewealth was negotiated and paid in full than those in the other categories.

Sixty-eight percent of currently married men age 15-49 have negotiated their bridewealth and paid it in full, while 12 percent negotiated the bridewealth and paid it partially. It is interesting to note that 19 percent of the married men did not negotiate the bridewealth payment.

The proportion of men who negotiated the bridewealth and paid it in full is higher in urban areas (71 percent) than rural areas (64 percent). Men from Northern region (89 percent) are most likely to negotiate the payment of bridewealth and pay it in full, while those in Brong Ahafo region (44 percent) are the least likely to do so. The percentage of men who negotiated the bridewealth and paid it in full fluctuates by wealth; it ranges from 74 percent among men in the fourth quintile to 59 percent for those in the second quintile.

Appendix **A**

A.1 INTRODUCTION

T he 2014 Ghana Demographic and Health Survey (GDHS) is the sixth in a series of Demographic and Health Surveys conducted in Ghana in 1988, 1993, 1998, 2003, and 2008. As with the prior surveys, the main objective of the 2014 GDHS is to provide up-to-date information on fertility and childhood mortality levels; fertility preferences; awareness, approval, and use of family planning methods; maternal and child health; knowledge and attitudes toward HIV/AIDS and other sexually transmitted infections (STI); and prevalence of HIV among the adult population. All women age 15-49 who are usual members of the selected households and others who spent the night before the survey in the selected households were eligible to be interviewed in the survey. In half of the sampled households, all men age 15-49 who were usual members of the selected households and those who spent the night before the survey in the selected households were eligible to be interviewed in the survey. In the same subsample, all women who were eligible for the survey and all children under age 5 were eligible for height and weight measuring and anaemia testing, and all women age 15-49 and men age 15-59 who were eligible for the individual survey were also eligible for HIV testing. The 2014 GDHS sample is designed to provide estimates of population and health indicators including fertility and mortality rates for the country as a whole, for urban and rural areas separately, and for each of the 10 geographical regions in Ghana.

The 2014 GDHS involved a two-stage sample design. This appendix describes the sampling frame used for the survey, the procedures used at each stage of the sample selection, and the necessity for and the steps followed in calculating the sample weights.

A.2 SAMPLING FRAME

The sampling frame used for the 2014 GDHS is the frame of the Ghana 2010 Population and Housing Census (PHC) provided by the Ghana Statistical Service (GSS). The census frame is a complete list of all census *enumeration areas* (EAs) created for the 2010 PHC. An EA is a geographic area covering an average of 145 households. The sampling frame contains information about the EA location, type of residence (urban or rural), and estimated number of residential households. A sketch map that delineates the EA geographic boundaries is available for each EA.

Administratively, Ghana is divided into ten geographical regions. Each region is further sub-divided into a number of districts, in total there are 170 districts. After the census, the government changed the second level administrative units by splitting some of them. Currently, there are 216 districts in Ghana. Table A.1 indicates the percentage distribution of households in the sampling frame by region and by type of residence. The regional distribution of households varies from 2 percent in Upper West to 21 percent in Ashanti. More than half of households in Ghana (56 percent) live in urban areas. The percentage of the population living in urban areas varies by region from 21 percent in Upper West to 92 percent in Greater Accra.

Table A.2 shows the distribution of EAs and their average size (average number of households) by region and by type of residence. There are in total 37,641 EAs in the sampling frame (excluding the institutional EAs), 16,503 in urban areas and 21,138 in rural areas. The average EA size is 145 households. Urban EAs have a larger average size than rural EAs (185 households per EA compared with 114 households per EA).

Table A.1 Households

Distribution of the households in the sampling frame by region and residence, Ghana 2014

| Region | Number of households in the frame | | | Percent distribution of households in the frame | |
	Urban	Rural	Total	Region	Urban
Western	248,919	304,716	553,635	10.1	45.0

A.3   SAMPLE DESIGN AND SELECTION

The 2014 GDHS sample was stratified and selected in two stages. Each region was stratified into urban and rural areas, yielding 20 sampling strata. Samples of EAs were selected independently in each stratum in two stages. Implicit stratification and proportional allocation were achieved at each of the lower administrative levels by sorting the sampling frame within each sampling stratum before sample selection, according to administrative units in different levels, and by using a probability proportional to size selection at the first stage of sampling.

In the first stage, 427 EAs were selected with probability proportional to the EA size and with independent selection in each sampling stratum. The EA size is the number of residential households residing in the EA enumerated in the 2010 PHC. A household listing operation was carried out in all the selected EAs, and the resulting lists of households served as a sampling frame for the selection of households in the second stage. To minimize the task of household listing for EAs with more than 200 households, each large EA was segmented. Only one segment was selected for the survey with probability proportional to the segment size. Household listing was conducted only in the selected segment. Therefore, a 2014 GDHS cluster is either an EA or a segment of an EA.

In the second stage of selection, a fixed number of 30 households per cluster was selected with an equal probability systematic selection from the newly created household listing. The survey interviewers visited and interviewed only the selected households. No replacements or changes of the selected

households were allowed during data collection, in order to prevent bias. All women age 15-49 who were usual members of the selected households or who spent the night before the survey in the selected households were eligible for the female survey. In half of the selected households, all men age 15-49 who were usual members of the households or who spent the night before the survey in the households were eligible for the male survey.

Table A.3 shows the allocation of clusters and selected households, and Table A.4 shows the expected number of completed women's and men's interviews, according to region and residence. To ensure that the survey precision is comparable across regions, the sample allocation figures a power allocation between regions and between different types of residence within each region. Based on a fixed sample take of 30 households per cluster, the survey selected 427 EAs, 216 in urban areas and 211 in rural areas. The survey was conducted in 12,810 residential households, 6,480 in urban areas and 6,330 in rural areas. The sample was expected to result in about 10,214 completed interviews with women age 15-49, 5,098 in urban areas and 5,116 in rural areas, and 4,175 completed interviews with men age 15-49, 2,061 in urban areas and 2,114 in rural areas.

Table A.3 Sample allocation of clusters and households

Sample allocation of clusters and households by region, according to residence, Ghana 2014

Region	Number of clusters			Number of households		
	Urban	Rural	Total	Urban	Rural	Total
Western	21	25	46	630	750	1,380
Central	22	23	45	660	690	1,350
Greater Accra	42	6	48	1,260	180	1,440
Volta	17	24	41	510	720	1,230
Eastern	22	25	47	660	750	1,410
Ashanti	32	17	49	960	510	1,470
Brong Ahafo	22	25	47	660	750	1,410
Northern	15	22	37	450	660	1,110
Upper East	13	22	35	390	660	1,050
Upper West	10	22	32	300	660	960
Ghana	216	211	427	6,480	6,330	12,810

Table A.4 Sample allocation of completed interviews with women and men

Sample allocation of expected number of completed interviews with women and men age 15-49 by region, according to residence, Ghana 2014

Region	Women 15-49			Men 15-49		
	Urban	Rural	Total	Urban	Rural	Total
Western	457	552	1,009	203	246	449
Central	476	506	982	178	189	367
Greater Accra	1,009	147	1,156	390	57	447
Volta	404	581	985	172	247	419
Eastern	472	546	1,018	199	230	429
Ashanti	782	422	1,204	295	160	455
Brong Ahafo	467	539	1,006	183	211	394
Northern	420	625	1,045	187	278	465
Upper East	327	562	889	139	239	378
Upper West	284	636	920	115	257	372
Ghana	5,098	5,116	10,214	2,061	2,114	4,175

The preceding calculations are based on the facts obtained from the 2008 GDHS: the average number of women age 15-49 per household is 0.87 in urban areas and 0.88 in rural areas; the average number of men age 15-49 per household is 0.65 in urban areas and 0.70 in rural areas. The household response rate is 94 percent in urban areas and 96 percent in rural areas; the women's response rate is 96 percent in both urban and rural areas, and the men's response rate is 96 percent in both urban and rural areas.

A.4 SAMPLE PROBABILITIES AND SAMPLE WEIGHTS

Due to the nonproportional allocation of sample to different regions and to their urban and rural areas, and the possible differences in response rates, sampling weights are required for any analysis using the 2014 GDHS data. These ensure the actual representative of the survey results at the national level as well as at the domain level. Because the 2014 GDHS sample is a two-stage stratified cluster sample, sampling weight will be calculated based on sampling probabilities separately for each sampling stage and for each cluster. We use the following notations:

P_{1hi}:   first-stage sampling probability of the ith cluster in stratum h
P_{2hi}:   second-stage sampling probability within the ith cluster (households)

Let a_h be the number of EAs selected in stratum h, M_{hi} the number of households according to the sampling frame in the ith EA, and $\sum M_{hi}$ the total number of households in the stratum. The probability of selecting the ith EA in the 2014 GDHS sample is calculated as follows:

$$\frac{a_h \, M_{hi}}{\sum M_{hi}}$$

Let b_{hi} be the proportion of households in the selected cluster compared to the total number of households in EA i in stratum h if the EA is segmented, otherwise $b_{hi} = 1$. Then the probability of selecting cluster i in the sample is:

$$P_{1hi} = \frac{a_h \, M_{hi}}{\sum M_{hi}} \times b_{hi}$$

Let L_{hi} be the number of households listed in the household listing operation in cluster i in stratum h, let g_{hi} be the number of households selected in the cluster. The second stage's selection probability for each household in the cluster is calculated as follows:

$$P_{2hi} = \frac{g_{hi}}{L_{hi}}$$

The overall selection probability of each household in cluster i of stratum h is therefore the production of the two stages of selection probabilities:

$$P_{hi} = P_{1hi} \times P_{2hi}$$

The sampling weight for each household in cluster i of stratum h is the inverse of its overall selection probability:

$$W_{hi} = 1 / P_{hi}$$

A spreadsheet containing all sampling parameters and selection probabilities was prepared to facilitate the calculation of the design weight. Design weight was adjusted for household as well as individual nonresponse to get the sampling weights for households and for women's and men's surveys respectively. The differences between the household sampling weights and the individual sampling weights are introduced by individual nonresponse. The final sampling weights are normalized to give the total number of unweighted cases equal to the total number of weighted cases at the national level, for both household and individual weights, respectively. The normalized weights are relative weights that are valid for estimating means, proportions, and ratios but not population totals and pooled data.

Table A.5 Sample implementation: Women

Percent distribution of households and eligible women by results of the household and individual interviews, and household, eligible women and overall women response rates, according to urban-rural residence and region (unweighted), Ghana 2014

[1] Includes all dried blood samples (DBS) tested at the lab and for which there is a result, i.e., positive, negative, or indeterminate. Indeterminate means that the sample went through the entire algorithm, but the final result was inconclusive.
[2] Includes (1) other results of blood collection (e.g., technical problem in the field), (2) lost specimens, (3) noncorresponding bar codes, and (4) other lab results such as blood not tested for technical reason, not enough blood to complete the algorithm, etc.
[3] A respondent is considered to have had concurrent partners if he or she had overlapping sexual partnerships with two or more people during the 12 months before the survey. (Respondents with concurrent partners include polygynous men who had overlapping sexual partnerships with two or more wives).

ESTIMATES OF SAMPLING ERRORS *Appendix* **B**

The estimates from a sample survey are affected by two types of errors: non-sampling errors and sampling errors. Non-sampling errors are the results of mistakes made in implementing data collection and data processing, such as failure to locate and interview the correct household, misunderstanding of the questions on the part of either the interviewer or the respondent, and data entry errors. Although numerous efforts were made during the implementation of the 2014 Ghana DHS (GDHS) to minimize this type of error, non-sampling errors are impossible to avoid and difficult to evaluate statistically.

Sampling errors, on the other hand, can be evaluated statistically. The sample of respondents selected in the 2014 GDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each of these samples would yield results that differ somewhat from the results of the actual sample selected. Sampling errors are a measure of the variability between all possible samples. Although the degree of variability is not known exactly, it can be estimated from the survey results.

Sampling error is usually measured in terms of the standard error for a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which the true value for the population can reasonably be assumed to fall. For example, for any given statistic calculated from a sample survey, the value of that statistic will fall within a range of plus or minus two times the standard error of that statistic in 95 percent of all possible samples of identical size and design.

If the sample of respondents had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the 2014 GDHS sample is the result of a multi-stage stratified design, and, consequently, it was necessary to use more complex formulae. Sampling errors are computed in either ISSA or SAS, using programs developed by ICF International. These programs use the Taylor linearization method of variance estimation for survey estimates that are means, proportions or ratios. The Jackknife repeated replication method is used for variance estimation of more complex statistics such as fertility and mortality rates.

The Taylor linearization method treats any percentage or average as a ratio estimate, $r = y/x$, where y represents the total sample value for variable y, and x represents the total number of cases in the group or subgroup under consideration. The variance of r is computed using the formula given below, with the standard error being the square root of the variance:

$$SE^2(r) = \text{var}(r) = \frac{1-f}{x^2} \sum_{h=1}^{H} \left[\frac{m_h}{m_h - 1} \left(\sum_{i=1}^{m_h} z_{hi}^2 - \frac{z_h^2}{m_h} \right) \right]$$

in which

$$z_{hi} = y_{hi} - r x_{hi} \text{, and } z_h = y_h - r x_h$$

where h represents the stratum which varies from 1 to H,

          m_h is the total number of clusters selected in the hth stratum,

          y_{hi} is the sum of the weighted values of variable y in the ith cluster in the hth stratum,

          x_{hi} is the sum of the weighted number of cases in the ith cluster in the hth stratum, and

          f is the overall sampling fraction, which is so small that it is ignored.

The Jackknife repeated replication method derives estimates of complex rates from each of several replications of the parent sample, and calculates standard errors for these estimates using simple formulae. Each replication considers *all but one* cluster in the calculation of the estimates. Pseudo-independent replications are thus created. In the 2014 GDHS, there were 427 non-empty Primary Sampling Unit (PSU). Hence, 427 replications were created. The variance of a rate r is calculated as follows:

$$SE^2(r) = var(r) = \frac{1}{k(k-1)} \sum_{i=1}^{k} (r_i - r)^2$$

in which

$$r_i = kr - (k-1)r_{(i)}$$

where r is the estimate computed from the full sample of 427 PSUs,
        $r_{(i)}$ is the estimate computed from the reduced sample of 426 PSUs (i^{th} PSU excluded), and
        k is the total number of PSUs.

In addition to the standard error, the design effect (DEFT) for each estimate is also calculated The design effect is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. Relative standard errors and confidence limits for the estimates are also calculated.

Sampling errors for the 2014 GDHS are calculated for selected variables considered to be of primary interest. The results are presented in this appendix for Ghana as a whole and for various residential categories: urban-rural and region. For each variable, the type of statistic (mean, proportion, or rate) and the base population are given in Table B.1. Tables B.2 through B.14 present the value of the statistic (R), its standard error (SE), the number of unweighted (N) and weighted (WN) cases, the design effect (DEFT), the relative standard error (SE/R), and the 95 percent confidence limits (R±2SE), for each variable. The sampling errors for mortality rates are presented for the five year period preceding the survey for the whole country and for the ten year period preceding the survey by residence and region. The DEFT is considered undefined when the standard error considering a simple random sample is zero (when the estimate is close to 0 or 1).

The confidence interval (e.g., as calculated for *the number of children ever born for women 40-49 years*) can be interpreted as follows: the overall average from the national sample is 4.830 and its standard error is 0.070. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., 4.830 ± 2×0.070. There is a high probability (95 percent) that the true proportion of women 40-49 with children ever born is between 4.691 and 4.969.

For the total sample, the value of the DEFT, averaged over all variables, is 1.484. This means that, due to multi-stage clustering of the sample, the average standard error is increased by a factor of 1.484 over that in an equivalent simple random sample.

Table B.1 List of variables for sampling errors, Ghana DHS 2014

Variable	Estimate	Base population
WOMEN		
Urban residence	Proportion	All women 15-49
No education	Proportion	All women 15-49
Secondary or higher education	Proportion	All women 15-49
Never married/in union	Proportion	All women 15-49
Currently married/in union	Proportion	All women 15-49
Married before age 20	Proportion	Women age 20-49
Had first sexual intercourse before age 18	Proportion	Women age 20-49
Currently pregnant	Proportion	All women 15-49
Children ever born	Mean	All women 15-49
Children surviving	Mean	All women 15-49
Children ever born to women age 40-49	Mean	Women age 40-49
Know any contraceptive method	Proportion	Currently married women 15-49
Know a modern method	Proportion	Currently married women 15-49
Currently using any method	Proportion	Currently married women 15-49
Currently using a modern method	Proportion	Currently married women 15-49
Currently using pill	Proportion	Currently married women 15-49
Currently using IUD	Proportion	Currently married women 15-49
Currently using condoms	Proportion	Currently married women 15-49
Currently using injectables	Proportion	Currently married women 15-49
Currently using female sterilisation	Proportion	Currently married women 15-49
Currently using rhythm method	Proportion	Currently married women 15-49
Currently using withdrawal	Proportion	Currently married women 15-49
Used public sector source	Proportion	Currently married women 15-49 using modern method
Want no more children	Proportion	Currently married women 15-49
Want to delay birth at least 2 years	Proportion	Currently married women 15-49
Ideal number of children	Mean	All women 15-49
Mothers received antenatal care for last birth	Proportion	Women with at least 1 live birth in past 5 years
Mothers protected against tetanus for last birth	Proportion	Women with at least 1 live birth in past 5 years
Births with skilled attendant at delivery	Proportion	Women with at least 1 live birth in past 5 years
Had diarrhoea in 2 weeks before survey	Proportion	Children under 5 years
Treated with ORS	Proportion	Children under 5 years with diarrhoea in past two weeks
Sought medical treatment for diarrhea	Proportion	Children under 5 years with diarrhoea in past two weeks
Vaccination card seen	Proportion	Children age 12-23 months
Received BCG vaccination	Proportion	Children age 12-23 months
Received pentavalent vaccination (3 doses)	Proportion	Children age 12-23 months
Received polio vaccination (3 doses)	Proportion	Children age 12-23 months
Received one dose of measles vaccination	Proportion	Children age 12-23 months
Received all basic vaccinations	Proportion	Children age 12-23 months
Height-for-age (-2SD)	Proportion	Children under 5 years who were measured
Weight-for-height (-2SD)	Proportion	Children under 5 years who were measured
Weight-for-age (-2SD)	Proportion	Children under 5 years who were measured
Body Mass Index (BMI) < 18.5	Proportion	All women 15-49 who were measured
Prevalence of anaemia (children 6-59 months)	Proportion	Children 6-59 months who were tested
Prevalence of anaemia (women 15-49)	Proportion	Women 15-49 who were tested
Had 2+ sexual partners in past 12 months	Proportion	All women 15-49
Condom use at last sex	Proportion	All women 15-49 who had sex in past 12 months
Abstinence among youth (never had sex)	Proportion	Never-married women 15-24
Sexually active in past 12 months among never-married youth	Proportion	Never-married women 15-24
Had an HIV test and received results in past 12 months	Proportion	All women 15-49
Accepting attitudes towards people with HIV	Proportion	All women 15-49
Total fertility rate (3 years)	Rate	Women years of exposure to child birth
Neonatal mortality[1]	Rate	Children exposed to the risk of mortality
Post-neonatal mortality[1]	Rate	Children exposed to the risk of mortality
Infant mortality[1]	Rate	Children exposed to the risk of mortality
Child mortality[1]	Rate	Children exposed to the risk of mortality
Under-5 mortality[1]	Rate	Children exposed to the risk of mortality
HIV prevalence among all women 15-49		All women 15-49 tested
MEN		
Urban residence	Proportion	All men 15-49
No education	Proportion	All men 15-49
Secondary or higher education	Proportion	All men 15-49
Never married/in union	Proportion	All men 15-49
Currently married/in union	Proportion	All men 15-49
Had first sexual intercourse before age 18	Proportion	Men age 25-49
Know any contraceptive method	Proportion	Currently married men 15-49
Know any modern contraceptive method	Proportion	Currently married men 15-49
Want no more children	Proportion	Currently married men 15-49
Want to delay birth at least 2 years	Proportion	Currently married men 15-49
Ideal number of children	Mean	All men 15-49
Had 2+ sexual partners in past 12 months	Proportion	All men 15-49
Condom use at last sex	Proportion	All men 15-49 who had sex in past 12 months
Abstinence among never married youth (never had sex)	Proportion	All never married men 15-24
Sexually active in past 12 months among never-married youth	Proportion	All never married men 15-24
Paid for sexual intercourse in past 12 months	Proportion	All men 15-49
Had HIV test and received results in past 12 months		All men 15-49
Accepting attitudes towards people with HIV		All men 15-49
HIV prevalence among all men 15-49		All men 15-49 tested
HIV prevalence among all men 15-59		All men 15-59 tested
WOMEN and MEN		
HIV prevalence among all women and men 15-49		All women and men 15-49 tested

[1] Mortality rates are calculated for 5 years and 10 years before the survey for the national sample regional samples, respectively

					Total	19,302	100.0	21,035	100.0

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview.

Table C.2.1 Age distribution of eligible and interviewed women

De facto household population of women age 10-54 and interviewed women age 15-49; and percent distribution and percentage of eligible women who were interviewed (weighted), by five-year age groups, Ghana 2014

Age group	Household population of women age 10-54	Interviewed women age 15-49		Percentage of eligible women interviewed
		Number	Percentage	
10-14	2,646	na	na	na
15-19	1,661	1,609	17.4	96.9
20-24	1,637	1,588	17.2	97.0
25-29	1,622	1,578	17.1	97.3
30-34	1,387	1,353	14.6	97.5
35-39	1,300	1,267	13.7	97.5
40-44	1,056	1,015	11.0	96.2
45-49	859	833	9.0	97.1
50-54	990	na	na	na
15-49	9,520	9,243	100.0	97.1

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview. Weights for both household population of women and interviewed women are household weights. Age is based on the Household Questionnaire.
na = Not applicable

Table C.2.2 Age distribution of eligible and interviewed men

De facto household population of men age 10-64 and interviewed men age 15-59; and percent distribution and percentage of eligible men who were interviewed (weighted), by five-year age groups, Ghana 2014

Age group	Household population of men age 10-59	Interviewed men age 15-59		Percentage of eligible men interviewed
		Number	Percentage	
10-14	1,392	na	na	na
15-19	870	839	19.6	96.4
20-24	598	568	13.3	94.9
25-29	612	582	13.6	95.1
30-34	570	529	12.4	92.8
35-39	495	464	10.9	93.9
40-44	464	436	10.2	93.9
45-49	377	351	8.2	93.1

55-59	222	211	4.9	95.0
60-64	261	na	na	na
15-59	4,521	4,275	100.0	94.6

Note: The de facto population includes all residents and nonresidents who stayed in the household the night before the interview. Weights for both household population of men and interviewed men are household weights. Age is based on the Household Questionnaire.
na = Not applicable

Table C.3 Completeness of reporting

Percentage of observations missing information for selected demographic and health questions (weighted), Ghana 2014

Subject	Reference group	Percentage with information missing	Number of cases
Birth date	Births in the 15 years preceding the survey		
Month only		1.46	15,421
Month and year		0.03	15,421
Age at death	Deceased children born in the 15 years preceding the survey	0.00	1,098
Age/date at first union[1]	Ever married women age 15-49	0.18	6,302
	Ever married men age 15-59	0.16	2,524
Respondent's education	All women age 15-49	0.00	9,396
	All men age 15-59	0.00	4,388
Diarrhoea in past 2 weeks	Living children 0-59 months	1.18	5,431
Anthropometry of children	Living children age 0-59 months (from the Household Questionnaire)		
Height		2.53	2,992
Weight		2.39	2,992
Height or weight		2.54	2,992
Anthropometry of women	Women age 15-49 (from the Household Questionnaire)		
Height		3.99	4,821
Weight		3.98	4,821
Height or weight		4.03	4,821
Anthropometry of men	Men age 15-59 (from the Household Questionnaire)		
Height		7.57	3,976
Weight		7.55	3,976
Height or weight		7.57	3,976
Anaemia			
Children	Living children age 6-59 months (from the Household Questionnaire)	3.53	2,662
Women	All women 15-49 (from the Household Questionnaire)	5.17	4,821

[1] Both year and age missing

Table C.4 Births by calendar years

Number of births, percentage with complete birth date, sex ratio at birth, and calendar year ratio by calendar year, according to living (L), dead (D), and total (T) children (weighted), Ghana 2014

Calendar year	Number of births			Percentage with complete birth date[1]			Sex ratio at birth[2]			Calendar year ratio[3]		
	Living	Dead	Total	Living	Dead	Total	Living	Dead	Total	Living	Dead	Total
2014	1,109	71	1,179	100.0	100.0	100.0	108.0	133.6	109.4	na	na	na

Note: Table is based on children who slept in the household the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the NCHS/CDC/WHO International Reference Population. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] Recumbent length is measured for children under age 2, or in the few cases when the age of the child is unknown and the child is less than 85cm; standing height is measured for all other children" to be consistent with table 11.1.1.
[2] Includes children who are below -3 standard deviations (SD) from the International Reference Population median
[3] Excludes children whose mothers were not interviewed
[4] First born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval
[5] Includes children whose mothers are deceased
[6] Excludes children whose mothers were not interviewed, children whose mothers were not weighed and measured, and children whose mothers are pregnant or gave birth within the preceding 2 months. Mother's nutritional status in terms of BMI (Body Mass Index) is presented in Table 11.10.1.
[7] For women who were not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

PARTICIPANTS IN THE 2014 GHANA DEMOGRAPHIC AND HEALTH SURVEY   *Appendix* **D**

PROJECT IMPLEMENTATION TEAM
Senior Project Management

Dr. Philomena Nyarko	Government Statistician/Project Director (GSS)
Baah Wadieh	Deputy Government Statistician/Deputy Project Director (GSS)
Anthony Amuzu	Acting Deputy Government Statistician/ Survey Director (GSS)
Sylvester Gyamfi	Director/Field Monitor (GSS)
David Kombat	Director/Field Monitor (GSS)
Peter Takyi Peprah	Project Coordinator (GSS)
Johnson Owusu Kagya	Trainer/Field Monitor (GSS)
Anthony Amuzu Pharin	Trainer/Field Monitor (GSS)
Godwin Odei Gyebi	Trainer/Field Monitor (GSS)
Emmanuel Boateng	Trainer/Field Monitor (GSS)
Abena Osei-Akoto	Data Processing Expert/Field Monitor (GSS)
Kwamena Arkafra	Data Processing Supervisor (GSS)
Betty-Love Hemans-Cobbinah	Internal Auditor (GSS)
Ben Gadzekpo	Senior Project Accountant (GSS)
Elizabeth Arhin Donkor	Assistant Project Accountant (GSS)

Regional Statisticians (GSS)

INTRODUCTION AND CONSENT

Hello. My name is _____. I am working with Ghana Statistical Service and the Ministry of Health. We are conducting a survey about health all over Ghana. The information we collect will help the government to plan health services. Your household was selected for the survey. I would like to ask you some questions about your household. The questions usually take about 15 to 20 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time.

In case you need more information about the survey, you may contact the person listed on this card.

GIVE CARD WITH CONTACT INFORMATION

Do you have any questions?

May I begin the interview now?

CODES FOR Qs. 17 AND 19: EDUCATION

LEVEL		GRADE
0 = PRE- PRIMARY	4 = SECONDARY	00 = LESS THAN 1 YEAR COMPLETED
1 = PRIMARY	5 = SSS/SHS	(USE '00' FOR Q. 17 ONLY.
2 = MIDDLE	6 = HIGHER	THIS CODE IS NOT ALLOWED
3 = JSS/JHS	8 = DON'T KNOW	FOR Q. 19)
		98 = DON'T KNOW

TABLE FOR SELECTION OF ONE CHILD FOR THE CHILD EDUCATION QUESTIONS

31	CHECK COLUMN 7:	MORE THAN ONE CHILD AGE 4-15:	ONLY ONE CHILD AGE 4-15	
	☐	ENTER TOTAL NUMBER IN BOX AND GO TO INSTRUCTIONS		→ 32
			NO CHILDREN AGE 4-15	→ 101

INSTRUCTIONS HOW TO USE THE SELECTION TABLE

LOOK AT THE LAST DIGIT OF THE EA (CLUSTER) NUMBER ON THE COVER PAGE. THIS IS THE ROW NUMBER YOU SHOULD CIRCLE IN THE TABLE. LOOK AT THE COLUM 7 AND COUNT THE TOTAL NUMBER OF ELIGIBLE CHILDREN AGE 4-15. THIS IS THE COLUMN NUMBER YOU SHOULD CIRCLE. FIND THE BOX WHERE THE CIRCLED ROW AND THE CIRCLED COLUMN MEET AND CIRCLE THE NUMBER THAT APPEARS IN THE BOX. THIS IS THE NUMBER OF THE ELIGIBLE CHILD WHOSE PARENT OR CARETAKER WILL BE ASKED THE QUESTIONS ON CHILD EDUCATION. THEN, GO TO COLUMN (1) AND PUT A * NEXT TO THE HOUSEHOLD LINE NUMBER OF THE SELECTED CHILD AND RECORD CHILD'S NAME AND HOUSEHOLD LINE NUMBER IN Q.32, AND RECORD CHILD'S PARENT OR OTHER MOST KNOWLEDGEABLE ADULT'S NAME AND LINE NUMBER IN Q.33.

FOR EXAMPLE , IF THE CLUSTER NUMBER IS '316', GO TO ROW 6 AND CIRCLE THE ROW NUMBER ('6'). IF THERE ARE THREE ELIGIBLE CHILDREN AGE 4-15 IN THE HOUSEHOLD, GO TO COLUMN 3 AND CIRCLE THE COLUMN NUMBER ('3'). DRAW LINES FROM ROW 6 AND COLUMN 3 AND FIND THE BOX WHERE THE TWO MEET, AND CIRCLE THE NUMBER IN IT ('2'). THIS MEANS YOU HAVE TO SELECT THE SECOND ELIGIBLE CHILD. SUPPOSE THE HOUSEHOLD LINE NUMBERS OF THE THREE ELIGIBLE CHILDREN ARE '02', '03', AND '07'; THEN THE ELIGIBLE CHILD FOR THE QUESTIONS ON CHILD EDUCATION IS THE SECOND ELIGIBLE CHILD, I.E., THE CHILD WITH HOUSEHOLD LINE NUMBER '03'. PUT A * NEXT TO THIS CHILD'S LINE NUMBER IN COLUMN (1) OF THE HOUSEHOLD SCHEDULE AND ALSO ENTER THE TWO DIGIT LINE NUMBER AND CHILD'S NAME IN Q.32. THEN, RECORD THE LINE NUMBER AND A NAME OF CHILD'S PARENT OT OTHER MOST, OR OTHER MOST KNOWLEDGEABLE ADULT IN Q.33.

LAST DIGIT OF THE EA (CLUSTER) NUMBER	TOTAL NUMBER OF CHILDREN AGE 4-15 IN THE HOUSEHOLD							
	1	2	3	4	5	6	7	8
0	1	2	2	4	3	6	5	4
1	1	1	3	1	4	1	6	5
2	1	2	1	2	5	2	7	6

210	ASK CONSENT FOR ANEMIA TEST FROM PARENT/OTHER ADULT IDENTIFIED IN 209 AS RESPONSIBLE FOR CHILD.	As part of this survey, we are asking that children all over the country take an anemia test. Anemia is a serious health problem that usually results from poor nutrition, infection, or chronic disease. This survey will assist the government to develop programs to prevent and treat anemia. We ask that all children born in 2009 or later take part in anemia testing in this survey and give a few drops of blood from a finger or heel. The equipment used to take the blood is clean and completely safe. It has never been used before and will be thrown away after each test. The blood will be tested for anemia immediately, and the result will be told to you right away. The result will be kept strictly confidential and will not be shared with anyone other than members of our survey team. Do you have any questions? You can say yes to the test, or you can say no. It is up to you to decide. Will you allow (NAME OF CHILD) to participate in the anemia test?

211A	ASK CONSENT FOR MALARIA TEST FROM PARENT/OTHER ADULT IDENTIFIED IN 209 AS RESPONSIBLE FOR CHILD.	As part of this survey, we are asking that children all over the country take a test to see if they have malaria. Malaria is a serious illness caused by a parasite transmitted by a mosquito bite. This survey will help the government to develop programs to prevent malaria. We ask that all children born in January 2009 or later take part in malaria testing in this survey and give a few drops of blood from a finger or heel. The equipment used to take the blood is clean and completely safe. It has never been used before and will be thrown away after each test. (We will use blood from the same finger prick made for the anemia test). One blood drop will be tested for malaria immediately, and the result will be told to you right away. A few blood drops will be collected on a slide and taken to a laboratory for testing. You will not be told the results of the laboratory testing. All results will be kept strictly confidential and will not be shared with anyone other than members of our survey team. Do you have any questions? You can say yes to the test, or you can say no. It is up to you to decide. Will you allow (NAME OF CHILD) to participate in the malaria testing?

210	ASK CONSENT FOR ANEMIA TEST FROM PARENT/OTHER ADULT IDENTIFIED IN 209 AS RESPONSIBLE FOR CHILD.	As part of this survey, we are asking that children all over the country take an anemia test. Anemia is a serious health problem that usually results from poor nutrition, infection, or chronic disease. This survey will assist the government to develop programs to prevent and treat anemia. We ask that all children born in 2009 or later take part in anemia testing in this survey and give a few drops of blood from a finger or heel. The equipment used to take the blood is clean and completely safe. It has never been used before and will be thrown away after each test. The blood will be tested for anemia immediately, and the result will be told to you right away. The result will be kept strictly confidential and will not be shared with anyone other than members of our survey team. Do you have any questions? You can say yes to the test, or you can say no. It is up to you to decide. Will you allow (NAME OF CHILD) to participate in the anemia test?

211A	ASK CONSENT FOR MALARIA TEST FROM PARENT/OTHER ADULT IDENTIFIED IN 209 AS RESPONSIBLE FOR CHILD.	As part of this survey, we are asking that children all over the country take a test to see if they have malaria. Malaria is a serious illness caused by a parasite transmitted by a mosquito bite. This survey will help the government to develop programs to prevent malaria. We ask that all children born in January 2009 or later take part in malaria testing in this survey and give a few drops of blood from a finger or heel. The equipment used to take the blood is clean and completely safe. It has never been used before and will be thrown away after each test. (We will use blood from the same finger prick made for the anemia test.) One blood drop will be tested for malaria immediately, and the result will be told to you right away. A few blood drops will be collected on a slide and taken to a laboratory for testing. You will not be told the results of the laboratory testing. All results will be kept strictly confidential and will not be shared with anyone other than members of our survey team. Do you have any questions? You can say yes to the test, or you can say no. It is up to you to decide. Will you allow (NAME OF CHILD) to participate in the malaria testing?

221	ASK CONSENT FOR ANEMIA TEST FROM PARENT/OTHER ADULT IDENTIFIED IN 220 AS RESPONSIBLE FOR NEVER IN UNION WOMEN AGE 15-17.	As part of this survey, we are asking people all over the country to take an anemia test. Anemia is a serious health problem that usually results from poor nutrition, infection, or chronic disease. This survey will assist the government to develop programs to prevent and treat anemia. For the anemia testing, we will need a few drops of blood from a finger. The equipment used to take the blood is clean and completely safe. It has never been used before and will be thrown away after each test. The blood will be tested for anemia immediately, and the result will be told to you and (NAME OF ADOLESCENT) right away. The result will be kept strictly confidential and will not be shared with anyone other than members of our survey team. You can say yes to the test for (NAME OF ADOLESCENT), or you can say no. It is up to you to decide. Will you allow (NAME OF ADOLESCENT) to take the anemia test? Do you have any questions?

228	ASK CONSENT FOR DBS COLLECTION FROM PARENT/OTHER ADULT IDENTIFIED IN 220 AS RESPONSIBLE FOR NEVER IN UNION WOMEN AGE 15-17.	As part of the survey we also are asking people all over the country to take an HIV test. HIV is the virus that causes AIDS. AIDS is a very serious illness. The HIV test is being done to see how big the AIDS problem is in Ghana. For the HIV test, we need a few (more) drops of blood from a finger. The equipment used to take the blood is clean and completely safe. It has never been used before and will be thrown away after each test. No names will be attached so we will not be able to tell you the test results. No one else will be able to know (NAME OF ADOLESCENT)'s test results either. If (NAME OF ADOLESCENT) wants to know her HIV status, I can provide a list of [nearby] facilities offering counseling and testing for HIV. I will also give her a voucher for free services that can be used at any of these facilities. Do you have any questions? You can say yes to the test, or you can say no. It is up to you to decide. Will you allow (NAME OF ADOLESCENT) to take the HIV test?

SECTION 1. RESPONDENT'S BACKGROUND

INTRODUCTION AND CONSENT

+---+
| INFORMED CONSENT |
| |
| Hello. My name is _____. I am working with |
| Ghana Statistical Service and the Ministry of Health. We are conducting a survey |
| about health all over Ghana. The information we collect will help the government |
| to plan health services. Your household was selected for the survey. The questions |
| usually take about 30-60 minutes. All of the answers you give will be confidential |
| and will not be shared with anyone other than members of our survey team. You don't |
| have to be in the survey, but we hope you will agree to answer the questions since |
| your views are important. If I ask you any question you don't want to answer, just |
| let me know and I will go on to the next question or you can stop the interview at |
| any time. |
| |
| In case you need more information about the survey, you may contact the person |
| listed on the card that has already been given to your household. |
| |
| Do you have any questions? May I begin the interview now? |
| |
| SIGNATURE OF INTERVIEWER: _____   DATE: _____ |
| |
| RESPONDENT AGREES TO BE INTERVIEWED ... 1   RESPONDENT DOES NOT AGREE TO BE |
| INTERVIEWED ... 2 → END |
+---+

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
101	RECORD THE TIME.	HOUR . . . . [ ][ ] MINUTES . . . . [ ][ ]	
101A	During the interview I would like to measure your blood pressure. This will be done three times during the interview. This is a harmless procedure. It is used to find out if a person has high blood pressure. If it is not treated, high blood pressure may eventually cause serious damage to the heart. The results of this blood pressure measurement will be given to you after the interview together with an explanation of the meaning of your blood pressure numbers. If your blood pressure is high, we will suggest that you consult a health facility or doctor since we cannot provide any further testing or treatment during the survey. Do you have any questions about the blood pressure measurement so far? If you have any questions about the procedure at any time, please ask me. You can say yes or no to having the blood pressure measurement now. You can also decide at anytime not to participate in the blood pressure measures. Would you allow me to proceed to take your blood pressure measurement at this time? Signature of interviewer: _____ Date: _____ RESPONDENT AGREES . . . . 1 RESPONDENT DOES NOT AGREE . . . . 2 → 102		
101B	Before taking your blood pressure, I would like to ask a few questions about things that may affect these measurements. Have you done any of the following within the past 30 minutes: a) Eaten anything? b) Had coffee, tea, cola or other drink that has caffeine? c) Smoked any tobacco product? d) Conducted any vigorous physical activity or exercises?	YES NO EATEN . . . . 1 2 HAD CAFFEINE . . . . 1 2 SMOKED . . . . 1 2 EXERCISES 1 2	

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
101C	May I begin the process of measuring your blood pressure? BEFORE TAKING THE FIRST BLOOD PRESSURE READING, MEASURE THE CIRCUMFERENCE OF THE RESPONDENT'S ARM MIDWAY BETWEEN THE ELBOW AND THE SHOULDER. RECORD THE MEASUREMENT IN CENTIMETERS.	ARM CIRCUMFERENCE (IN CENTIMETRES) . . . . ☐☐	
101D	USE THE ARM CIRCUMFERENCE MEASUREMENT TO SELECT THE APPROPRIATE BLOOD PRESSURE MONITOR MODEL AND CUFF SIZE. CIRCLE THE CODE FOR THE MODEL AND CUFF SIZE.	**MODEL 767** SMALL: 16 CM – 23 CM . . . . 1 MEDIUM: 24 CM – 35 CM . . . . 2 LARGE: 36 CM – 41 CM . . . . 3 **MODEL 789** EXTRA LARGE: 42 CM – 60 CM 4

308 — In what month and year was the sterilization performed?

308A — Since what month and year have you been using (CURRENT METHOD) without stopping?

PROBE: For how long have you been using (CURRENT METHOD) now without stopping?

MONTH . . . .

YEAR . . . .

---

309 — CHECK 308/308A, 215 AND 231:

ANY BIRTH OR PREGNANCY TERMINATION AFTER MONTH AND YEAR OF START OF USE OF CONTRACEPTION IN 308/308A

YES ☐   NO ☐

GO BACK TO 308/308A, PROBE AND RECORD MONTH AND YEAR AT START OF CONTINUOUS USE OF CURRENT METHOD (MUST BE AFTER LAST BIRTH OR PREGNANCY TERMINATION).

---

310 — CHECK 308/308A:

YEAR IS 2009 OR LATER ☐

C ENTER CODE FOR METHOD USED IN MONTH OF INTERVIEW IN THE CALENDAR AND IN EACH MONTH BACK TO THE DATE STARTED USING.

YEAR IS 2008 OR EARLIER ☐

C ENTER CODE FOR METHOD USED IN MONTH OF INTERVIEW IN THE CALENDAR AND EACH MONTH BACK TO JANUARY 2009.

THEN SKIP TO ⟶ 322

---

311 — I would like to ask you some questions about the times you or your partner may have used a method to avoid getting pregnant during the last few years.

USE CALENDAR TO PROBE FOR EARLIER PERIODS OF USE AND NONUSE, STARTING WITH MOST RECENT USE, BACK TO JANUARY 2009.
USE NAMES OF CHILDREN, DATES OF BIRTH, AND PERIODS OF PREGNANCY AS REFERENCE POINTS.

C **IN COLUMN 1**, ENTER METHOD USE CODE OR '0' FOR NONUSE IN EACH BLANK MONTH.

ILLUSTRATIVE QUESTIONS:
a) When was the last time you used a method? Which method was that?
b) When did you start using that method? How long after the birth of (NAME)?
c) How long did you use the method then?

IN COLUMN 2, ENTER CODES FOR DISCONTINUATION NEXT TO THE LAST MONTH OF USE. NUMBER OF CODES IN COLUMN 2 MUST BE SAME AS NUMBER OF INTERRUPTIONS OF METHOD USE IN COLUMN 1.

ASK WHY SHE STOPPED USING THE METHOD. IF A PREGNANCY FOLLOWED, ASK WHETHER SHE BECAME PREGNANT UNINTENTIONALLY WHILE USING THE METHOD OR DELIBERATELY STOPPED TO GET PREGNANT.

ILLUSTRATIVE QUESTIONS:
d) Why did you stop using the (METHOD)? Did you become pregnant while using (METHOD), or did you stop to get pregnant, or did you stop for some other reason?
e) IF DELIBERATELY STOPPED TO BECOME PREGNANT, ASK: How many months did it take you to get pregnant after you stopped using (METHOD)? AND ENTER '0' IN EACH SUCH MONTH IN COLUMN 1.

---

1106	CALCULATE THE AVERAGE SYSTOLIC AND DIASTOLIC PRESSURES BY DIVIDING THE SUM IN Q1105 BY 2.	AVERAGE SYSTOLIC □□□ AVERAGE DIASTOLIC □□□	→ 1111
1107	CHECK Q1056: SYSTOLIC <u>AND</u> DIASTOLIC BLOOD PRESSURE NOT RECORDED IN Q1056 □ BOTH SYSTOLIC <u>AND</u> DIASTOLIC BLOOD PRESSURE RECORDED IN Q1056 □		→ 1110
1108	CHECK Q600C: SYSTOLIC <u>AND</u> DIASTOLIC BLOOD PRESSURE NOT RECORDED IN Q600C □ BOTH SYSTOLIC <u>AND</u> DIASTOLIC BLOOD PRESSURE RECORDED IN Q600C □		→ 1110
1109	CHECK Q101E: SYSTOLIC <u>AND</u> DIASTOLIC BLOOD PRESSURE RECORDED IN Q101E □ BOTH SYSTOLIC <u>AND</u> DIASTOLIC BLOOD PRESSURE <u>**NOT**</u> RECORDED IN Q101E □		→ 1113
1110	RECORD THE SYSTOLIC AND DIASTOLIC PRESSURE.	SYSTOLIC □□□ DIASTOLIC □□□	

1111	USE THE TABLE BELOW TO DETERMINE THE CORRECT CODE TO RECORD ON THE BLOOD PRESSURE REPORT AND REFERRAL FORM.

CIRCLE THE **ROW** IN WHICH THE VALUE FOR THE **SYSTOLIC** BLOOD PRESSURE
FROM Q1106 OR Q1110 IS FOUND.

THEN CIRCLE THE **COLUMN** IN WHICH THE VALUE FOR THE **DIASTOLIC** BLOOD
FROM Q1106 OR Q1110 IS FOUND.

THE VALUE WHERE THE ROW AND COLUMN YOU HAVE CIRCLED INTERSECT IN THE TABLE WILL
BE USED IN COMPLETING Q1112.

AVERAGE SYSTOLIC PRESSURE	AVERAGE DIASTOLIC PRESSURE					
	<84	85-89	90-99	100-109	110-119	$\geq$ 120
≤129	1	2	3	4	5	6
130-139	2	2	3	4	5	6
140-159	3	3	3	4	5	6
160-179	4	4	4	4	5	6
180-209	5	5	5	5	5	6
$\geq$ 210	6	6	6	6	6	6

1112	RECORD THE NUMBER YOU CIRCLED IN Q1111 IN THE CHART BELOW. THEN USE THE INSTRUCTIONS TO THE RIGHT OF THAT NUMBER TO COMPLETE A BLOOD PRESSURE REPORT AND REFERRAL FORM FOR THE RESPONDENT. GIVE THE FORM TO THE RESPONDENT AND ANSWER ANY QUESTIONS SHE MAY HAVE.

	RESPONDENT'S BLOOD PRESSURE CATEGORY	CONSULT HEALTH PROVIDER TO CHECK BLOOD PRESSURE <u>WITHIN</u>:
1	NORMAL	**24 MONTHS**
2	AT THE HIGH END OF THE NORMAL RANGE	**12 MONTHS**
3	ABOVE NORMAL RANGE	**2 MONTHS**
4	MODERATELY HIGH	**1 MONTH**
5	VERY HIGH	**7 DAYS**
6	EXTREMELY HIGH	**TODAY**

1113	Thank you for taking the time to answer these questions. I would like to inform you that additional information on childbearing and contraception will be collected in the near future in order to find better ways to help couples in Ghana achieve their family goals. Another member of our team may return in a few days or weeks to ask you a few additional questions about these topics. Do you agree to allow another member of our team to contact you about participating in a short interview? Your responses will remain confidential.	YES · 1 NO · 2

INTRODUCTION AND CONSENT

INFORMED CONSENT

Hello. My name is _____. I am working with Ghana Statistical Service and the Ministry of Health. We are conducting a survey about health all over Ghana. The information we collect will help the government to plan health services. Your household was selected for the survey. The questions usually take about 20 minutes. All of the answers you give will be confidential and will not be shared with anyone other than members of our survey team. You don't have to be in the survey, but we hope you will agree to answer the questions since your views are important. If I ask you any question you don't want to answer, just let me know and I will go on to the next question or you can stop the interview at any time.

In case you need more information about the survey, you may contact the person listed on the card that has already been given to your household.

Do you have any questions? May I begin the interview now?

SIGNATURE OF INTERVIEWER: _____   DATE: _____

RESPONDENT AGREES TO BE INTERVIEWED   1   RESPONDENT DOES NOT AGREE TO BE INTERVIEWED . . .   2 → END

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
101	RECORD THE TIME.	HOUR . . . . ☐☐ MINUTES . . . . ☐☐	
101A	During the interview I would like to measure your blood pressure. This will be done three times during the interview. This is a harmless procedure. It is used to find out if a person has high blood pressure. If it is not treated, high blood pressure may eventually cause serious damage to the heart. The results of this blood pressure measurement will be given to you after the interview together with an explanation of the meaning of your blood pressure numbers. If your blood pressure is high, we will suggest that you consult a health facility or doctor since we cannot provide any further testing or treatment during the survey. Do you have any questions about the blood pressure measurement so far? If you have any questions about the procedure at any time, please ask me. You can say yes or no to having the blood pressure measurement now. You can also decide at anytime not to participate in the blood pressure measures. Would you allow me to proceed to take your blood pressure measurement at this time? Signature of interviewer: _____ Date: _____ RESPONDENT AGREES . . . . 1 RESPONDENT DOES NOT AGREE . . . . 2 → 102		
101B	Before taking your blood pressure, I would like to ask a few questions about things that may affect these measurements. Have you done any of the following within the past 30 minutes: a) Eaten anything? b) Had coffee, tea, cola or other drink that has caffeine? c) Smoked any tobacco product? d) Conducted any vigorous physical activity or exercises?	YES NO EATEN . . . . 1 2 HAD CAFFEINATED DRINK . 1 2 SMOKED . . . . 1 2 EXERCISES 1 2	

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
101C	May I begin the process of measuring your blood pressure? BEFORE TAKING THE FIRST BLOOD PRESSURE READING, MEASURE THE CIRCUMFERENCE OF THE RESPONDENT'S ARM MIDWAY BETWEEN THE ELBOW AND THE SHOULDER. RECORD THE MEASUREMENT IN CENTIMETERS.	ARM CIRCUMFERENCE (IN CENTIMETRES) . . . . ☐☐	
101D	USE THE ARM CIRCUMFERENCE MEASUREMENT TO SELECT THE APPROPRIATE BLOOD PRESSURE MONITOR MODEL AND CUFF SIZE. CIRCLE THE CODE FOR THE MODEL AND CUFF SIZE.	**MODEL 767** SMALL: 16 CM – 23 CM . . . . 1 MEDIUM: 24 CM – 35 CM . . . . 2 LARGE: 36 CM – 41 CM . . . . 3 **MODEL 789** EXTRA LARGE: 42 CM – 60 CM 4	
101E	TAKE THE FIRST BLOOD PRESSURE READING. RECORD THE SYSTOLIC AND DIASTOLIC PRESSURE. THEN PROCEED TO Q.102 IF YOU ARE UNABLE TO MEASURE THE RESPONDENT'S BLOOD PRESSURE, RECORD THE REASON.	SYSTOLIC . . . . ☐☐☐ DIASTOLIC . . . . ☐☐☐ REFUSED .994 TECHNICAL PROBLEMS . . . . 995 OTHER 996	
102	In what month and year were you born?	MONTH . . . . ☐☐ DON'T KNOW MONTH . . . . 98 YEAR . . . . ☐☐☐☐ DON'T KNOW YEAR 9998	
103	How old were you at your last birthday? COMPARE AND CORRECT 102 AND/OR 103 IF INCONSISTENT.	AGE IN COMPLETED YEARS ☐☐	
104	Have you ever attended school?	YES . . . . 1 NO 2	→ 108
105	What is the highest level of school you attended: primary, middle/JSS/JHS, secondary/SSS/SHS, or higher?	PRIMARY . . . . 1 MIDDLE . . . . 2 JSS/JHS . . . . 3 SECONDARY . . . . 4 SSS/SHS . . . . 5 HIGHER 6	
106	What is the highest (grade) you completed at that level? IF COMPLETED LESS THAN ONE YEAR AT THAT LEVEL, RECORD '00'.	GRADE . . . . ☐☐	
106A	CHECK 103: AGE 24 OR YOUNGER ☐ AGE 25 OR OLDER ☐ ——————————→ ↓		107
106B	At what age did you enroll in primary school?	AGE IN COMPLETED YEARS ☐☐	
106C	Are you currently attending school at any level?	YES . . . . 1 NO 2	→ 107

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
106D	Why did you stop attending school?	HAD TO WORK . . . . 01 MOVED . . . . 02 NO MONEY TO COVER COSTS . . . . . 03 HAD BAD GRADES . . . . 04 HEALTH REASONS . . . . 05 GOT MARRIED/ FAMILY REASONS . . 06 COMPLETED DESIRED LEVEL . . . . . 07 NO DESIRE TO CONTINUE . . . . 08 OTHER _____ 96 SPECIFY	
107	CHECK 105: PRIMARY/MIDDLE/ ☐ SECONDARY/ ☐ JSS/JHS SSS/SHS OR HIGHER		→ 110

108	Now I would like you to read this sentence to me.
